<sup>1</sup> A skilled provider includes a doctor, auxiliary nurse midwife, nurse, midwife, lady health visitor, and other health personnel. For birth attendance, if the woman mentioned more than one person attending the delivery, only the most qualified person is considered in this table.

Table 8.32 Birth order and delivery characteristics by state/union territory

Percentage of births to women age 15-49 during the 3 years preceding the survey of birth order 3 or more, percentage of women who had a live birth in the 5 years preceding the survey by antenatal care (ANC) provider during pregnancy for the most recent live birth, by state/union territory, India, 2019-21

| State/union territory                | Percentage of births of order 3 or more | Percentage of births receiving antenatal care from a doctor | Percentage of births receiving antenatal care from an ANM/nurse/midwife/LHV |

ANM = Auxiliary nurse midwife; LHV = Lady health visitor

### Key Findings

- **Birth weight:** Eighty-one percent of live births in the five years preceding the survey had a written record of the child's weight at the time of birth or the mother was able to recall the child's weight. Eighteen percent of these births had a low birth weight (less than 2.5 kg), the same as in 2015-16.
- **Vaccination coverage:** Seventy-seven percent of children age 12-23 months received all basic vaccinations, up from 62 percent in 2015-16. Over four-fifths (84%) of children received three doses of hepatitis B vaccine.
- **Symptoms of acute respiratory infection (ARI):** Three percent of children under five years had symptoms of ARI in the two weeks before the survey; advice or treatment was sought from a health facility or provider for 56 percent of those children.
- **Diarrhoea:** Seven percent of children under age five years had diarrhoea in the two weeks before the survey; advice or treatment was sought from a health facility or provider for 76 percent of those children. Forty-five percent of children with diarrhoea received continued feeding and oral rehydration therapy (ORT), as recommended.
- **Disposal of children's stools:** Only 38 percent of young children's stools are disposed of safely.
- **Integrated Child Development Services (ICDS) for children under age six years:** Sixty-eight percent of children received any service from an *anganwadi* centre. Sixty-two percent received food supplements.
- **Services from ICDS during pregnancy and while breastfeeding:** Seventy percent of pregnant women and 66 percent of breastfeeding women received any service from an *anganwadi* centre.

Information on child health and survival can help policymakers and programme managers assess the efficacy of current strategies, formulate appropriate interventions to prevent deaths from childhood illnesses, and improve the health of children in India.

This chapter presents information on birth weight and vaccination status for young children. It also provides estimates of the prevalence of, and treatment practices for, three common childhood illnesses: symptoms of acute respiratory infection (ARI), fever, and diarrhoea. Since appropriate sanitary practices can help in preventing and reduce the severity of diarrhoeal disease, information is also provided on the disposal of children's stools.

## 9.1 BIRTH WEIGHT

### Low birth weight

Births with a reported birth weight less than 2.5 kg regardless of gestational age

**Sample:** Live births in the five years before the survey that have a reported birth weight, either from a written record or mother's report

Birth weight is an important indicator when assessing a child's health for early exposure to childhood morbidity and mortality. Children who weigh less than 2.5 kilograms (kg) at birth are considered to have a higher-than-average risk of early childhood death. In the 2019-21 National Family Health Survey, birth weight was recorded from either a written record or the mother's report. The mother's estimate of the infant's size at birth was also obtained because the birth weight is unknown for many infants.

For 91 percent of births, a written record of birth weight was available or the mother was able to recall the birth weight (**Table 9.1**). Eighteen percent of these infants had a low birth weight of less than 2.5 kg. Low birth weight decreases with an increase in the mother's schooling and household wealth status. Only 16 percent of births to mothers having 12 or more years of schooling have a low birth weight, compared with 20 percent of births to mothers having no schooling. Similarly, 15 percent of births to mothers in households in the highest wealth quintile have a low birth weight, compared with 21 percent of births to mothers in the lowest wealth quintile households. The pattern of birth weight by background characteristics may be affected by the availability of birth weight records or the mother's recall and should be interpreted with caution.

**Table 9.1** also includes information on the mother's estimate of her infant's size at birth. The mother's estimate of size is subjective but can be a useful proxy for the child's weight. Three percent of births are reported as very small, 8 percent as smaller than average, and 88 percent as average or larger than average.

## 9.2 VACCINATION OF CHILDREN

Immunizing children against vaccine preventable diseases can greatly reduce childhood morbidity and mortality. Information on vaccination coverage was collected from the child's health card and direct reporting from the mother.

### Coverage of all basic vaccinations

Children age 12-23 months who received specific vaccines at any time before the survey (according to a vaccination card or the mother's report). To have received all basic vaccinations, a child must receive at least:

- one dose of BCG vaccine, which protects against tuberculosis
- three doses of DPT vaccine, which protects against diphtheria, pertussis (whooping cough), and tetanus
- three doses of polio vaccine
- one dose of measles vaccine

**Sample:** Living children age 12-23 months

In India, 77 percent of children age 12-23 months received all basic vaccinations at any time before the survey, and 67 percent received all basic vaccinations by age 12 months (**Table 9.3**).

## Figure 9.1 Childhood Vaccinations

Percentage of children age 12-23 months

**Figure 9.1** shows the coverage for each of the basic vaccinations among children age 12-23 months. Coverage was highest for the BCG vaccine (95%) and lowest for the third dose of polio vaccine (81%). Although more children received the first doses of the DPT and polio vaccines than the second or third doses, the dropout rates are higher for polio than for DPT (**Table 9.4**). Ninety-four percent of children age 12-23 months received the first DPT dose and 87 percent received the last dose. These percentages were 92 percent and 81 percent for the polio vaccine. Four percent of children age 12-23 months received no vaccinations. Eighty-four percent of children received three doses of hepatitis B vaccine.

**Trends:** The percentage of children age 12-23 months who have received all basic vaccinations increased from 62 percent in 2015-16 to 77 percent in 2019-21 (**Figure 9.2**). Between 2015-16 and 2019-21, this percentage increased more in rural areas (from 61% to 77%) than in urban areas (from 64% to 76%). The proportion of children who received no vaccinations declined from 6 percent in 2015-16 to 4 percent in 2019-21.

## Figure 9.2 Trends in Childhood Vaccinations

Percentage of children age 12-23 months

## Patterns by background characteristics

- Children age 12-23 months of first birth order are much more likely to receive all basic vaccinations than children of birth order 6 or more (78% versus 59%) (**Table 9.4**).
- Vaccination coverage increases with increasing mother's schooling; 80 percent of children age 12-23 months whose mothers have 12 or more years of schooling have received all basic vaccinations, compared with 68 percent of children whose mothers have no schooling (**Figure 9.3**).

**Figure 9.3 Coverage with All Basic Vaccinations by Mother's Schooling**

*Percentage of children age 12-23 months*

- Muslim children are less likely to receive all basic vaccinations.
- Vaccination coverage increases with increasing wealth status; 79 percent of children age 12-23 months from households in the highest wealth quintile received all basic vaccinations, compared with 71 percent of children from households in the lowest wealth quintile.
- Coverage of all basic vaccinations varies considerably by state and union territory. The coverage is highest in Dadra & Nagar Haveli and Daman & Diu (95%), Odisha (91%), Tamil Nadu (89%), and Himachal Pradesh (89%) and lowest in Nagaland (58%), Meghalaya (64%) and Arunachal Pradesh (65%) (**Table 9.5** and **Figure 9.4**).

Vaccination cards are a critical tool in ensuring that a child receives all recommended vaccinations on schedule. All mothers were not able to produce a vaccination card for their child at the time of the interview; vaccination cards were available for 86 percent of children age 12-23 months which is a large increase from 63 percent in 2015-16 (**Table 9.4**).

More than 70 percent of children age 12-23 months are fully vaccinated in the majority of districts of the country. In only a few districts is this percentage lower than 50 percent, and most of these districts are in the northeastern states.

**Figure 9.4 Coverage with All Basic Vaccinations by State/UT**

*Percentage of children age 12-23 months*

**Map 9.1: Children age 12-23 months fully vaccinated based on information from either vaccination card or mother's recall, NFHS-5, 2019-21**

### 9.3 SYMPTOMS OF ACUTE RESPIRATORY INFECTION

Mothers reported that 3 percent of children under age five years had symptoms of acute respiratory infection (ARI) in the two weeks before the survey. The prevalence of symptoms of ARI is highest among children whose mother smokes cigarettes/tobacco, whose mothers completed less than 5 years of schooling, children age 6-11 months, and Buddhists/Neo-Buddhists (4% each) (**Table 9.7**).

#### **Treatment of acute respiratory infection (ARI) symptoms**

Children with ARI symptoms for whom advice or treatment was sought. ARI symptoms consist of cough accompanied by (1) short, rapid breathing that is chest related, and/or (2) difficult breathing that is chest related.

**Sample:** Children under age five years with symptoms of ARI in the two weeks before the survey

Advice or treatment was sought for 56 percent of children under age five years with ARI symptoms in the two weeks before the survey (**Table 9.7**); advice or treatment was sought the same or the next day for 39 percent of children (**Table 9.8**). Seeking advice or treatment ranges from 13 percent in Nagaland to 100 percent in Chandigarh and Goa. Seeking advice or treatment the same day or the next day ranges from 11 percent in Nagaland to 100 percent in Chandigarh and Goa.

### 9.4 FEVER

Fever is a symptom of malaria, but it is also associated with other childhood illnesses that may contribute to high levels of malnutrition, morbidity, and mortality in young children.

#### **Treatment of fever**

Children with fever for whom advice or treatment was sought.

**Sample:** Children under age five years with fever in the two weeks before the survey

Among children under age five years, 13 percent had fever in the two weeks before the survey. The prevalence of fever peaks at 20 percent among Buddhist/Neo-Buddhist children, followed by 18 percent among children age 6-11 months (**Table 9.9**). Eighty percent of children with fever were taken to a health facility or provider for advice or treatment, and advice or treatment was sought the same day or the next day for 59 percent of children. Twenty-five percent of children under age five years with fever were given antibiotic drugs.

### 9.5 DIARRHOEAL DISEASE

#### 9.5.1 Prevalence of Diarrhoea

Mothers reported that 7 percent of children under age five years had diarrhoea in the two weeks before the survey (**Table 9.10**). Advice or treatment was sought for 76 percent of children under age five years who had diarrhoea in the two weeks before the survey (**Table 9.11**).

The prevalence of diarrhoea in the two weeks preceding the survey among children below age 5 years is less than 10 percent in most of the districts of India. In only 29 districts is prevalence of diarrhoea more than 15 percent, which includes 4 districts in Bihar with more than 20 percent.

Map 9.2

## Patterns by background characteristics

- The prevalence of diarrhoea rises from 8 percent among children under age six months to 13 percent among those age 6-11 months, when complementary foods and other liquids are supposed to be introduced. Prevalence decreases to 10 percent at age 12-23 months, which is the time when children begin to walk and are at increased risk of contamination from the environment (**Figure 9.5**).
- Differences by other characteristics are generally quite small.

**Figure 9.5 Prevalence of Diarrhoea by Age**

*Percentage of children under age five years*

### 9.5.2 Treatment of Diarrhoea

#### **Oral rehydration therapy**

Children with diarrhoea are given increased fluids or a fluid made from a special packet of oral rehydration salt (ORS) or gruel.

**Sample:** Children under age five years with diarrhoea in the two weeks before the survey

Oral rehydration therapy (ORT) is a simple and effective way to reduce dehydration caused by diarrhoea. Sixty-eight percent of children with diarrhoea received some form of ORT—ORS packets (61%) or gruel (34%) or increased fluids (5%) (**Figure 9.6**). While 17 percent of children received antibiotics, 24 percent were given both zinc and ORS, which can reduce the duration and severity of diarrhoea. Forty-five percent received continued feeding and ORT, as recommended. Fifteen percent of children with diarrhoea did not receive any treatment.

**Trends:** The proportion of children with diarrhoea who received fluid from ORS packets increased from 51 percent in 2015-16 to 61 percent in 2019-21. The percentage of children who did not receive any treatment decreased from 18 percent in 2015-16 to 15 percent in 2019-21.

### Figure 9.6 Treatment of Diarrhoea

Percentage of children under age five years with diarrhoea in the two weeks before the survey

#### Patterns by background characteristics

- Urban children with diarrhoea are more likely than rural children to receive fluid from an ORS packet (63% versus 60%) (Table 9.11).
- The use of ORS packets for the treatment of diarrhoea among the states/UTs ranges from 45 percent in Goa to 88 percent in Dadra & Nagar Haveli and Daman & Diu.
- Children in households in the lowest wealth quintile (67%) are less likely to be given some form of ORT than children in households in the highest wealth quintile (73%).

### Figure 9.7 Prevalence and Treatment of Childhood Illness

Percentage of children under age five years with symptoms of illness in the two weeks before the survey and percentage with an illness for whom advice or treatment was sought a from health facility or provider

### 9.5.3 Feeding Practices

#### Appropriate feeding practices

Children with diarrhoea are given more liquids than usual, and as much food or more food than usual.

**Sample:** Children under age five years with diarrhoea in the two weeks before the survey

To reduce dehydration and minimise the effects of diarrhoea on nutritional status, mothers are encouraged to continue normal feeding of children with diarrhoea and to increase the amount of fluids.

Only 5 percent of children under five years with diarrhoea in the two weeks before the survey were given more liquids than usual, as recommended. Thirty-one percent received the same amount of liquids. Of greater concern, 59 percent of children with diarrhoea were given less to drink and 5 percent were not given anything to drink (**Figure 9.8**). Only 30 percent of children with diarrhoea were fed according to the recommended practice of giving the same amount of food or more food to the sick child. Sixty percent of children were given less food than usual, while 2 percent who had previously been given food received no food during the diarrhoea.

For additional information on feeding practices during diarrhoea, see **Table 9.13** and **Table 9.14**.

#### Figure 9.8 Feeding Practices during Diarrhoea

*Percentage of children under age five years with diarrhoea in the two weeks before the survey*

### 9.5.4 Knowledge of ORS Packets

Ninety-four percent of women in India know about ORS packets for the treatment of diarrhoea (**Table 9.15**). Knowledge of ORS packets is highest among Jain women (98%), followed closely by Christian women, women with 12 or more years of schooling, and women in the wealthiest households (97% each).

## 9.6 DISPOSAL OF CHILDREN'S STOOLS

### Safe disposal of children's stools

The child's last stools were put or rinsed into a toilet or latrine, buried, or the child used a toilet or latrine.

**Sample:** Youngest child under age five years living with the mother

Proper disposal of children's faeces is important to prevent the spread of disease. Only 38 percent of youngest children under age five years living with their mother had their last stools disposed of appropriately (**Table 9.16**).

### Patterns by background characteristics

- Children's stools are more likely to be disposed of appropriately in households with an improved toilet facility that is not shared (47%) or a shared toilet (42%) than in households with an unimproved facility or no facility (32%).
- Children's stools are much more likely to be disposed of appropriately in urban households (55%) than in rural households (32%).
- Stools are disposed of appropriately for 50 percent of children of mothers with 12 or more years of schooling, compared with only 25 percent of children of mothers with no schooling.
- Stools are appropriately disposed of for 66 percent of children in households belonging to the highest wealth quintile, compared with only 17 percent of children in households in the lowest wealth quintile.
- The proportion of children whose stools are disposed of appropriately varies from 13 percent in Odisha and 20 percent in Jharkhand and Assam to 83 percent in Kerala and 91 percent in Lakshadweep.

## 9.7 UTILIZATION OF INTEGRATED CHILD DEVELOPMENT SERVICES (ICDS)

Established in 1975 under India's largest ICDS programme, *anganwadi* centres (AWCs) provide health, nutrition, and education services for children from birth to six years of age, as well as nutritional and health services for pregnant and breastfeeding mothers. The programme is implemented through a network of community-level *anganwadi* centres.

Sixty-eight percent of children under age six years receive one or more services from an AWC (**Table 9.18**). The provision of food supplements is the service most likely to be used (62%), but 51-60 percent receive growth monitoring, immunizations, health check-ups, and early childhood care or preschool services.

### Patterns by background characteristics

- Rural children are more likely to receive any service from an AWC (72%) than urban children (56%).
- The proportion of children receiving supplementary food from an *anganwadi* centre ranges from 35 percent in Arunachal Pradesh to 87 percent in Odisha.

### 9.7.1 Utilization of ICDS by Pregnant and Lactating Mothers

Pregnant and lactating mothers can receive supplementary food from an *anganwadi* centre. *Anganwadi* centres also monitor the health status of mothers during pregnancy and breastfeeding and provide them with health and nutritional education.

Only 30 percent of mothers did not receive any AWC services during pregnancy for their children under six years, and 34 percent did not receive any service from an AWC while breastfeeding children born in the six years preceding the survey. Pregnant and breastfeeding mothers were more likely to have received supplementary food (66% and 64%, respectively) than health check-ups (63% and 58%, respectively) or health and nutrition education (60% and 56%, respectively).

#### Patterns by background characteristics

- Services during pregnancy and while breastfeeding are utilized more for births to women in rural areas than urban areas.
- The percentage of women receiving supplementary food during pregnancy and while breastfeeding is higher in almost all states than the percentage receiving health check-ups or health and nutrition education in 28 of the 36 states/UTs.

## LIST OF TABLES

For more information on low birth weight, vaccinations, childhood illness, the disposal of children's stools, and the utilization of ICDS services, see the following tables:

| Tables     |                                                                                                        |

Note: Children are considered to have received the vaccine if it was either written on the child's vaccination card or reported by the mother. For children whose vaccination information is based on the mother's report, the date of vaccination is not collected. The proportions of vaccinations given during the first and second years of life are assumed to be the same as for children with a written record of vaccination.

na = Not applicable

<sup>1</sup> Vaccination card or other document where vaccinations are recorded

<sup>2</sup> Received by age 12 months for all vaccines except MCV 2, which should be received by age 18 months and Japanese encephalitis by 24 months

<sup>3</sup> For children whose vaccination information is based on the mother's report, date of vaccination is not collected. The proportions of vaccinations given during the first and second years of life are assumed to be the same as for children with a written record of vaccinations.

<sup>4</sup> For children age 12-23 months, BCG, MCV/measles/MMR/MR, and three doses each of DPT/Penta and polio vaccine (excluding polio vaccine given at birth). For children age 24-35 months, BCG, two doses of MCV/measles/MMR/MR, four doses of hepatitis B, three doses each of DPT/Penta and polio vaccine (excluding polio vaccine given at birth), three doses of rotavirus vaccine, and two doses of Japanese encephalitis vaccine.

<sup>5</sup> BCG, MCV/Measles/MMR/MR, and three doses each of DPT/Penta and polio vaccine (excluding polio vaccine given at birth)

**Table 9.4 Vaccinations by background characteristics**

Percentage of children age 12-23 months who received specific vaccines at any time before the survey (according to a vaccination card or the mother's report), and percentage with a vaccination card seen, by background characteristics, India, 2019-21

Note: Children are considered to have received the vaccine if it was either written on the child's vaccination card or reported by the mother. For children whose vaccination information is based on the mother's report, the date of vaccination is not collected. The proportions of vaccinations given during the first and second years of life are assumed to be the same as for children with a written record of vaccination.

<sup>1</sup> Hepatitis B 0 is the hepatitis vaccination given at birth

<sup>2</sup> Polio 0 is the polio vaccination given at birth

<sup>3</sup> BCG, MCV/ Measles/MMR/MR, and three doses each of DPT/Penta and polio vaccine (excluding polio vaccine given at birth)

<sup>4</sup> BCG, MCV/ Measles/MMR/MR, four doses of hepatitis B, and three doses each of DPT/Penta and polio vaccine (excluding polio vaccine given at birth)

<sup>5</sup> Child has not received any vaccinations listed in the table

Table 9.5 Vaccinations by state/union territory

Note: Children are considered to have received the vaccine if it was either written on the child's vaccination card or reported by the mother. For children whose vaccination information is based on the mother's report, the date of vaccination is not collected. The proportions of vaccinations given during the first and second years of life are assumed to be the same as for children with a written record of vaccination.

<sup>1</sup> Hepatitis B 0 is the hepatitis vaccination given at birth

<sup>2</sup> Polio 0 is the polio vaccination given at birth

<sup>3</sup> BCG, MCV/Measles/MMR/MR, and three doses each of DPT/Penta and polio vaccine (excluding polio vaccine given at birth)

<sup>4</sup> BCG, MCV/Measles/MMR/MR, four doses of hepatitis B, and three doses each of DPT/Penta and polio vaccine (excluding polio vaccine given at birth)

<sup>5</sup> Child has not received any vaccinations listed in the table

Table 9.6 Trends over time in vaccinations

Percentage of children age 12-23 months who received specific vaccines at any time before the survey (according to a vaccination card or the mother's report), and percentage with a vaccination card seen, by residence, India

| Vaccinations given any time before the survey | Urban               |                     | Rural               |                     | Total               |                     |

<sup>1</sup> For NFHS-5, Penta is included in this row. Penta was not included in the NFHS-4 questionnaire, so Penta is not included in the NFHS-4 vaccination coverage for DPT/Hepatitis.

<sup>2</sup> Polio 0 is the polio vaccination given at birth

<sup>3</sup> Hepatitis B 0 is the hepatitis vaccination given at birth

<sup>4</sup> BCG, MCV/Measles/MMR/MR, and three doses each of DPT/Penta and polio vaccine (excluding polio vaccine given at birth)

Table 9.7 Prevalence and treatment of symptoms of ARI

Among children under age 5 years, percentage who had symptoms of acute respiratory infection (ARI) in the 2 weeks preceding the survey and among children with symptoms of ARI in the 2 weeks preceding the survey, percentage for whom advice or treatment was sought from a health facility or provider, by background characteristics, India, 2019-21

| Background characteristic | Among children under age 5 years             |                    | Among children under age 5 years with symptoms of ARI                                              |                                                                                 |                    |

<sup>1</sup> Children's stools are considered to be disposed of appropriately if the child used a toilet or latrine, if the fecal matter was put/rinsed into a toilet or latrine, or if it was buried

<sup>2</sup> See Table 2.2 for definition of categories

<sup>3</sup> Facilities that would be considered improved if they were not shared by two or more households

Table 9.17 Disposal of children's stools by state/union territory

Percent distribution of mothers with a child under age 2 years living with the mother by the manner of disposing of the youngest child's last stools and percentage with children whose stools were disposed of appropriately, according to state/union territory, India, 2019-21

| State/union territory                | Manner of disposal of children's stools |                                   |                                |                   |        |                  |       |                    | Total | Percentage of children whose stools are disposed of appropriately <sup>1</sup> |

<sup>1</sup> Children's stools are considered to be disposed of safely if the child used a toilet or latrine, if the fecal matter was put/rinsed into a toilet or latrine or if it was buried

Table 9.18 Indicators of utilization of ICDS services

Percentage of living children under age 6 years who received any service from an *anganwadi* centre (AWC) in the 12 months preceding the survey, percentage who received specific services from an AWC in the 12 months preceding the survey, and among children age 0-59 months who were weighed at an AWC in the 12 months preceding the survey, percentage whose mothers received counselling from an AWC after the child was weighed, by background characteristics, India, 2019-21

| Background characteristic | Percentage of children age 0-71 months who received any service | Percentage of children under age 6 years who: |                        |                           |                                                       |                           | Number of children under age 6 years | Percentage whose mothers received counselling from an AWC after child was weighed |                |

ICDS = Integrated Child Development Services

<sup>1</sup> Supplementary food includes both food cooked and served at an AWC on a daily basis or given in the form of take home rations

<sup>2</sup> Children age 36-71 months

<sup>3</sup> Children age 0-59 months

**Table 9.19 Indicators of utilization of ICDS services by state/union territory**

Percentage of living children under age 6 years who received any service from an *anganwadi* centre (AWC) in the 12 months preceding the survey, percentage who received specific services from an AWC in the 12 months preceding the survey, and among children age 0-59 months who were weighed at an AWC in the 12 months preceding the survey, percentage whose mothers received counselling from an AWC after the child was weighed, by state/union territory, India, 2019-21

| State/union territory                | Percentage of children age 0-71 months who received any service | Percentage of children under age 6 years who: |                           |                                                        |                           |      | Percentage whose mothers received counselling from an AWC after child was weighed |

ICDS = Integrated Child Development Services

<sup>1</sup> Supplementary food includes both food cooked and served at an AWC on a daily basis or given in the form of take home rations

<sup>2</sup> Children age 36-71 months

<sup>3</sup> Children age 0-59 months

Table 9.20 Utilization of ICDS services during pregnancy and while breastfeeding

Among children under age 6 years, percentage whose mothers received specific services from an *anganwadi* centre (AWC) during pregnancy and while breastfeeding, according to background characteristics, India, 2019-21

| Background characteristic | Mother received from an AWC during pregnancy |                                 |                  |                                |                    | Mother received from an AWC while breastfeeding <sup>2</sup> |                                 |                  |                                |                              |

ICDS = Integrated Child Development Services

<sup>1</sup> Supplementary food includes both food cooked and served at the AWC on a daily basis or given in the form of take home rations

<sup>2</sup> Excludes children who were not breastfed. Services are usually provided to breastfeeding mothers during the first 6 months of breastfeeding

Table 9.21 Women's utilization of ICDS services during pregnancy and while breastfeeding by state/union territory

Among children under age 6 years, percentage whose mothers received specific services from an *anganwadi* centre (AWC) during pregnancy and while breastfeeding, by state/union territory, India, 2019-21

| State/union territory                | Mother received from an AWC during pregnancy |                                 |                  |                                | Mother received from an AWC while breastfeeding <sup>2</sup> |                                 |                  |                                |

ICDS = Integrated Child Development Services

<sup>1</sup> Supplementary food includes both food cooked and served at the AWC on a daily basis or given in the form of take home rations

<sup>2</sup> Excludes children who were not breastfed. Services are usually provided to breastfeeding mothers during the first 6 months of breastfeeding

## Key Findings

- **Nutritional status of children:** Thirty-six percent of children under age five years are stunted (short for their age); 19 percent are wasted (thin for their height); 32 percent are underweight (thin for their age); and 3 percent are overweight (heavy for their height). Children born to mothers with no schooling and children in the lowest wealth quintile are most likely to be undernourished.
- **Initial breastfeeding:** About two-fifths (41%) of children born in the last 5 years were breastfed within 1 hour of birth, as recommended. Timely initiation of breastfeeding is particularly low for women with no schooling, for home deliveries, and for births delivered by a *dai*.
- **Exclusive breastfeeding:** Sixty-four percent of children under age six months are exclusively breastfed.
- **Anaemia among children:** Sixty-seven percent of children age 6-59 months have anaemia (haemoglobin levels below 11.0 g/dl), which is higher than the NFHS-4 estimate of 59 percent.
- **Micronutrient intake:** Thirty-seven percent of children age 6-59 months were given vitamin A supplements in the six months preceding the survey. Forty-seven percent of children age 6-23 months consumed foods rich in vitamin A in the day or night before the interview and 21 percent consumed iron-rich foods.
- **Deworming:** Thirty percent of children age 6-59 months received deworming medication in the past six months.
- **Nutritional status of adults:** Nineteen percent of women and 16 percent of men age 15-49 are thin. Almost the same percentage are overweight or obese (24% of women and 23% of men).
- **WHR of adults:** Fifty-seven percent of women and 48 percent of men have waist-to-hip ratio (WHR) that puts them at a substantial increased risk of metabolic complications.
- **Anaemia among adults:** Fifty-seven percent of women and 25 percent of men age 15-49 have anaemia.

**T**his chapter focuses on the nutritional status of children and adults, examining the types of food consumed and the consequences of inadequate nutrition and poor infant and child feeding practices. The chapter also addresses the diversity of food consumed by women and men age 15-49 years, as well as the prevalence of anaemia and malnutrition.

## 10.1 NUTRITIONAL STATUS OF CHILDREN

The anthropometric data on height and weight collected in the 2019-21 NFHS permit the measurement and evaluation of the nutritional status of young children in India. This evaluation allows identification of subgroups of the child population that are at increased risk of faltered growth, disease, impaired mental development, and death.

### 10.1.1 Nutritional Status among Young Children

The 2019-21 NFHS measured the weight and height of children under age five years regardless of whether their mothers were interviewed in the survey. Weight was measured with an electronic SECA 874 flat scale designed for mobile use. For the weighing of very young children, the mother or caretaker was weighed first. The mother or caretaker was weighed again while holding the child. An automatic two-in-one adjustment button allowed the mother's stored weight to be deducted and the baby's weight to be displayed on the scale. Height was measured with a Seca 213 stadiometer. Children younger than age 24 months were measured lying down (recumbent length using a Seca 417 infantometer), while standing height was measured for the older children.

Children's height/length, weight, and age data were used to calculate three indices: height-for-age, weight-for-height, and weight-for-age. Each of these indices provides different information about growth and body composition for assessing nutritional status, as indicated in the box below. Stunting, or low height-for-age, is a sign of chronic undernutrition that reflects failure to receive adequate nutrition over a long period. Stunting can also be affected by recurrent and chronic illness. Wasting, or low weight-for-height, is a measure of acute undernutrition and represents the failure to receive adequate nutrition in the period immediately before the survey. Wasting may result from inadequate food intake or from a recent episode of illness causing weight loss. The opposite of wasting is overweight (high weight-for-height), a measure of overnutrition. Weight-for-age is a composite index that takes into account both acute and chronic undernutrition.

#### **Stunting (assessed via height-for-age)**

Height-for-age is a measure of linear growth retardation and cumulative growth deficits. Children whose height-for-age Z-score is below minus two standard deviations (-2 SD) from the median of the reference population are considered short for their age (stunted), or chronically undernourished. Children who are below minus three standard deviations (-3 SD) are considered severely stunted.

**Sample:** Children under age five years

#### **Wasting (assessed via weight-for-height)**

Weight-for-height index measures body mass in relation to body height or length and describes current nutritional status. Children whose Z-score is below minus two standard deviations (-2 SD) from the median of the reference population are considered thin (wasted), or acutely undernourished. Children whose weight-for-height Z-score is below minus three standard deviations (-3 SD) from the median of the reference population are considered severely wasted.

**Sample:** Children under age five years

#### **Underweight (assessed via weight-for-age)**

Weight-for-age is a composite index of height-for-age and weight-for-height. It takes into account both acute and chronic undernutrition. Children whose weight-for-age Z-score is below minus two standard deviations (-2 SD) from the median of the reference population are classified as underweight. Children whose weight-for-age Z-score is below minus three standard deviations (-3 SD) from the median are considered severely underweight.

**Sample:** Children under age five years

### Overweight children

Children whose weight-for-height Z-score is more than 2 standard deviations (+2 SD) above the median of the reference population are considered overweight.

**Sample:** Children under age five years

The means of the z-scores for height-for-age, weight-for-height, and weight-for-age are also calculated as summary statistics representing the nutritional status of children in a population. These mean scores describe the nutritional status of the entire population of children without the use of a cut-off point. A mean Z-score of less than zero (i.e., a negative mean value for stunting, wasting, or underweight) suggests a downward shift in the entire sample population's nutritional status relative to the reference population. The farther away the mean z-scores are from zero, the higher is the prevalence of undernutrition.

### 10.1.2 Levels of Child Malnutrition

In India, 36 percent of children under age five years are stunted (too short for their age). This is a sign of chronic undernutrition. Nineteen percent of children under age five years are wasted (too thin for their height), which is a sign of acute undernutrition, while 32 percent of children under age five years are underweight. Three percent of children are overweight (**Table 10.1**).

**Trends:** The prevalence of stunting and under-weight has decreased since 2015-16. Stunting declined from 38 percent in 2015-16 to 36 percent in 2019-21. Over this same time period, the prevalence of wasting has declined from 21 percent in 2015-16 to 19 percent in 2019-21 (**Figure 10.1**).

**Figure 10.1 Trends in Nutritional Status of Children**

Percentage of children age 0-59 months

### Patterns by background characteristics

- The prevalence of undernutrition is almost the same among girls and boys, although girls are slightly less well nourished than boys on all three measures (**Table 10.1**).
- The prevalence of stunting increases with a child's age from 6-8 months through 6-23 months, and it decreases slightly thereafter.
- Over two-fifths (44%) of children who were reported to be very small at birth are stunted, compared with 35 percent of children who were of average size or larger.
- Children born to thin mothers (BMI less than 18.5 kg/m<sup>2</sup>) are more likely to be stunted, wasted, and underweight than children born to mothers with a normal BMI or children whose mothers are overweight/obese.
- Stunting is higher among children in rural areas (37%) than urban areas (30%).
- Forty-six percent of children born to mothers with no schooling are stunted, compared with 26 percent of children born to mothers with 12 or more years of schooling. The corresponding proportions of underweight children are 42 and 23 percent, respectively.
- The prevalence of stunting decreases steadily with an increase in wealth quintiles, from 46 percent of children in households in the lowest wealth quintile to 23 percent of children in households in the highest wealth quintile.

- The prevalence of stunting in children under age five is the highest in Meghalaya (47%), followed by Bihar (43%) and Uttar Pradesh and Jharkhand (40% each), and it is lowest in Puducherry (20%) and Sikkim (22%). Bihar has the highest level of underweight children (41%). Maharashtra has the highest level of wasting (26%) (**Figure 10.2**).

*Percentage of children age 0-59 months*

## 10.2 INFANT AND YOUNG CHILD FEEDING PRACTICES

Appropriate infant and young child feeding (IYCF) practices include exclusive breastfeeding in the first six months of life, continued breastfeeding through age two years, introduction of solid and semi-solid foods at age six months, and gradual increases in the amount of food given and the frequency of feeding as the child gets older. It is also important for young children to receive a diverse diet, i.e., eating foods from different food groups to take care of the growing micronutrient needs.

### 10.2.1 Initiation of Breastfeeding

Early initiation of breastfeeding is important for both the mother and the child. The first breastmilk contains colostrum, which is highly nutritious and has antibodies that protect the newborn from diseases. Early initiation of breastfeeding also encourages bonding between the mother and her newborn, facilitating the production of regular breastmilk. Thus, it is recommended that children be put to the breast immediately or within one hour after birth and that prelacteal feeding (i.e., feeding newborns anything other than breastmilk before breastmilk is regularly given) be discouraged.

#### Early breastfeeding

Initiation of breastfeeding within one hour of birth

**Sample:** Last-born children who were born in the two years before the survey

**Table 10.4** shows that 96 percent of children born in the two years before the survey were breastfed at some time. There are no major differences by background characteristics. About two-fifths (41%) of last-born children in the two

years before the survey who ever breastfed were breastfed within one hour of birth, and 87 percent of children began breastfeeding within one day of birth. Sixteen percent of children received a prelacteal feed.

### Early breastfeeding practices by background characteristics

- Children whose delivery was assisted by health personnel (42%) or who were born at a place other than a home or health facility (43%) were more likely to start breastfeeding within one hour of birth than other children.
- The percentage of children that are breastfed within one hour of birth is very low in Jharkhand (22%); the only states in which more than two-thirds of children are breastfed within one hour of birth are Odisha, Kerala, Lakshadweep, and Meghalaya (**Table 10.5**).
- Prelacteal feeding ranges from a minimum of 3 percent of children in Lakshadweep to a maximum of 31 percent of children in Chandigarh and Nagaland.

### 10.2.2 Exclusive Breastfeeding

Breastmilk contains all of the nutrients needed by children in the first six months of life and is an uncontaminated nutritional source. It is recommended that children be exclusively breastfed in the first six months of their life; that is, they are given nothing but breastmilk. Complementing breastmilk before age six months is unnecessary and is discouraged because the likelihood of contamination and the resulting risk of diarrhoeal disease are high. Early initiation of complementary feeding also reduces breastmilk output because the production and release of breastmilk is modulated by the frequency and intensity of suckling.

**Table 10.6** and **Figure 10.3** show breastfeeding practices by children's age. Sixty-four percent of infants under age six months are exclusively breastfed. Contrary to the recommendation that children under age six months be exclusively breastfed, many children in that age group consume other liquids, such as plain water (10%), other milk (8%), or complementary foods (11%) in addition to breastmilk.

**Trends:** Exclusive breastfeeding among children under six months increased from 55 percent in 2015-16 to 64 percent in 2019-21.

### 10.2.3 Median Duration of Breastfeeding

The median duration of breastfeeding in India is 32.1 months. This means that half of children have stopped breastfeeding by age about 32 months (**Table 10.7**). The median duration of exclusive breastfeeding is 3.9 months, and the median duration of predominant breastfeeding (the period in which an infant receives only water or other non-milk liquids in addition to breastmilk) is 5.8 months.

**Trends:** The median duration of exclusive breastfeeding increased from 2.9 months in 2015-16 to 3.9 months in 2019-21. The median duration of any breastfeeding also increased, from 29.6 months to 32.1 months.

**Figure 10.3 Breastfeeding Practices by Age**

*Percentage of children under age two years*

### Patterns by background characteristics

- On average, children in rural areas are breastfed longer (median duration of 33.5 months) than their counterparts in urban areas (median duration of 25.8 months).
- On average, children of scheduled caste and scheduled tribe mothers are breastfed longer (median duration of more than 36 months) than the children whose mothers belong to other backward classes (median duration of 29.3 months) and children not from scheduled castes, scheduled tribes, or other backward classes (median duration of 31.4 months).
- The median duration of breastfeeding is 36.0 months or longer in ten states (Chandigarh, Jammu and Kashmir, Chhattisgarh, Jharkhand, Odisha, West Bengal, Arunachal Pradesh, Assam, Manipur, and Tripura), and is shortest in Andaman and Nicobar Islands (15.4 months) (**Table 10.8**).

#### 10.2.4 Complementary Feeding

After the first six months, breastmilk is no longer enough to meet the nutritional needs of the infant; therefore, complementary foods should be added to the diet of the child. Appropriate complementary feeding should include a variety of foods to ensure that requirements for nutrients are met. Fruits and vegetables rich in vitamin A should be consumed daily. Eating a range of fruits and vegetables, in addition to those rich in vitamin A, is also important.

**Table 10.9** shows that the type of foods and liquids received by children during the day and night before the survey depends on the child's age and breastfeeding status. Overall, foods made from grains are the most consumed complementary food items irrespective of breastfeeding status, followed by fruits and vegetables rich in vitamin A.

### Patterns by background characteristics

- For children age 6-23 months, consumption of liquids other than milk is lower among breastfed children (34%) than among nonbreastfed children (43%).
- Fewer breastfed (41%) children age 6-23 months eat fruits and vegetables rich in vitamin A than nonbreastfeeding children (48%).
- Among children age 6-23 months, the least consumed food items are fortified baby foods for breastfed and nonbreastfed children (16% each).

#### 10.2.5 Minimum Acceptable Diet

Infants and young children should be fed a minimum acceptable diet (MAD) to ensure appropriate growth and development. Without adequate diversity and meal frequency, infants and young children are vulnerable to undernutrition, especially stunting and micronutrient deficiencies, and to increased morbidity and mortality. The WHO minimum acceptable diet recommendation, which is a combination of dietary diversity and minimum meal frequency, is different for breastfed and nonbreastfed children. The definition of the composite indicator of a minimum acceptable diet for all children 6-23 months is indicated in the box below.

Dietary diversity is a proxy for adequate micronutrient-density of foods. Minimum dietary diversity means feeding the child food from at least four food groups. The cut-off of four food groups is associated with better-quality diets for both breastfed and nonbreastfed children.

The minimum meal frequency is a proxy for a child's energy requirements. For infants and young children, the indicator is based on how much energy the child needs and, if the child is breastfed, the amount of energy needs not met by breastmilk. Breastfed children are considered to be consuming a minimum meal frequency if they receive solid, semi-solid, or soft foods at least twice a day for infants 6-8 months and at least three times a day for children 9-23 months.

Nonbreastfed children ages 6-23 months are considered to be fed with a minimum meal frequency if they receive solid, semi-solid, or soft foods at least four times a day.

### Minimum acceptable diet

Proportion of children age 6-23 months who receive a minimum acceptable diet. This indicator is a composite of the following two groups:

Breastfed children age 6-23 months who had at least the minimum dietary diversity and the minimum meal frequency during the previous day

Breastfed children age 6-23 months

and

Nonbreastfed children age 6-23 months who received at least two milk feedings, and had at least the minimum dietary diversity (not including milk feeds), and the minimum meal frequency during the previous day

Nonbreastfed children age 6-23 months

The 2019-21 NFHS indicates that 94 percent of youngest children age 6-23 months living with their mothers received breastmilk, milk, or milk products (2+ times) during the day or night before the interview (**Table 10.10**). Twenty-four percent of breastfed children had an adequately diverse diet since they had been given foods from the appropriate number of food groups, while 31 percent had been fed the minimum number of times appropriate for their age. The feeding practices of only 11 percent of breastfed children age 6-23 months meet the minimum standards for all IYCF feeding practices. Eleven percent of all children age 6-23 months were fed the minimum acceptable diet. The IYCF indicators for minimum acceptable diet by breastfeeding status among the youngest children age 6-23 months are summarised in **Figure 10.4**.

**Figure 10.4 IYCF Indicators on Minimum Acceptable Diet (MAD)**

Percentage of children age 6-23 months

### Patterns by background characteristics

- Breastfed children age 6-23 months are more likely than non-breastfed children age 6-23 months to receive the minimum number of food groups (24% and 17%, respectively).
- Children in urban areas and rural areas have an almost equal adequately diverse diet (24% and 23%, respectively).
- Breastfed infants and non-breastfed infants are almost equally likely to meet the minimum acceptable diets (11% and 12%, respectively).
- The percentage of children age 6-23 months who receive a minimum acceptable diet generally increases with the mother's schooling. For example, only 9 percent of children whose mothers have no schooling receive a minimum acceptable diet, compared with 12 percent of children whose mothers have 12 or more years of schooling.

- The proportion of children age 6-23 months who receive a minimum acceptable diet is highest in Meghalaya (29%) and the lowest in Uttar Pradesh and Gujarat (6% each). The pattern is the same among breastfed children (**Table 10.11**).

### 10.3 ANAEMIA PREVALENCE IN CHILDREN

#### Anaemia in children

| Anaemia status                                                                                 | Haemoglobin level in grams/decilitre* |
|------------------------------------------------------------------------------------------------|---------------------------------------|
| Anaemic                                                                                        | <11.0                                 |
| Mildly anaemic                                                                                 | 10.0-10.9                             |
| Moderately anaemic                                                                             | 7.0-9.9                               |
| Severely anaemic                                                                               | <7.0                                  |
| Not anaemic                                                                                    | 11.0 or higher                        |
| *Haemoglobin levels are adjusted for altitude in enumeration areas that are above 1,000 metres |                                       |

**Sample:** Children 6-59 months

Anaemia is a condition that is marked by low levels of haemoglobin in the blood. Iron is a key component of haemoglobin, and iron deficiency is estimated to be responsible for half of all anaemia globally. Other causes of anaemia include malaria, hookworm and other helminths, other nutritional deficiencies, chronic infections, and genetic conditions. Anaemia is a serious concern for children because it can impair cognitive development, stunt growth, and increase morbidity from infectious diseases.

In the 2019-21 NFHS, haemoglobin testing was performed on children age 6-59 months. The testing was successfully completed for 91 percent of the children eligible for testing. The methodology used to measure haemoglobin is described in Chapter 1.

Overall, 67 percent of children had some degree of anaemia (haemoglobin levels below 11.0 g/dl). Twenty-nine percent of children had mild anaemia, 36 percent had moderate anaemia, and 2 percent had severe anaemia (**Table 10.12**).

**Trends:** Between 2015-16 and 2019-21, the prevalence of anaemia among children age 6-59 months increased from 59 percent to 67 percent and continued to be higher among rural children (**Table 10.12**).

#### Patterns by background characteristics

- Anaemia is more prevalent among children under age 35 months than among older children, with a peak prevalence of 80 percent observed among children age 12-17 months (**Table 10.12**).
- Anaemia prevalence increases with increasing birth order of children and is higher among the children of anaemic mothers than non-anaemic mothers.
- The prevalence of anaemia declines as the mother's schooling and household wealth increase.

The prevalence of anaemia among children age 6-59 months is highest among children in Gujarat (80%), followed by Madhya Pradesh (73%), Rajasthan (72%), and Punjab (71%). Several union territories have even higher prevalence of anaemia—Ladakh (94%), Dadar & Nager Haveli and Daman & Diu (76%), and Jammu & Kashmir (73%). The states with the lowest prevalence of anaemia among children are Kerala (39%), Andaman & Nicobar Islands (40%), and Nagaland and Manipur (43% each) (**Table 10.13**).

**Figure 10.5 Trends in Childhood Anaemia**

Percentage of children age 6-59 months

## 10.4 PRESENCE OF IODIZED SALT IN HOUSEHOLDS

Iodine is an essential micronutrient, and iodized salt prevents goitre or any other thyroid-related health problems among children and adults. It is recommended that household salt should be fortified with iodine to at least 15 parts per million (ppm).

The 2019-21 NFHS tested for the presence or absence of potassium iodate or potassium iodide in household salt. Salt was tested in almost all households (**Table 10.15**). Among the households in which salt was tested, 94 percent had iodized salt. This is similar to NFHS-4, when 93 percent of households were using iodized salt. There is steady increase in the use of iodized salt by household wealth quintiles, from 91 percent in the lowest wealth quintile to 97 percent in the highest wealth quintile. Among the states, the use of iodized salt is lowest in Andhra Pradesh (83%), Dadra & Nagar Haveli and Daman & Diu (89%), and Meghalaya (91%) (**Table 10.16**).

## 10.5 MICRONUTRIENT INTAKE AND SUPPLEMENTATION AMONG CHILDREN

Micronutrient deficiency is a major contributor to childhood morbidity and mortality. Micronutrients are available in foods and can also be provided through direct supplementation. Breastfeeding children benefit from supplements given to the mother.

The information collected on food consumption among the youngest children under age two years is useful in assessing the extent to which children are consuming foods rich in two key micronutrients—vitamin A and iron—in their daily diet. Iron deficiency is one of the primary causes of anaemia, which has serious health consequences for both women and children. Vitamin A is an essential micronutrient for the immune system and plays an important role in maintaining the epithelial tissue in the body. Severe vitamin A deficiency (VAD) can cause eye damage and is the leading cause of childhood blindness. VAD also increases the severity of infections such as measles and diarrhoeal disease in children and slows recovery from illness. VAD is common in dry environments where fresh fruits and vegetables are not readily available.

Forty-seven percent of children age 6-23 months consumed foods rich in vitamin A in the day or night before the interview, and 21 percent consumed iron-rich foods (**Table 10.17**). The intake of both vitamin A-rich and iron-rich foods increases as children are weaned.

Among children age 6-59 months, 27 percent were given iron supplements in the seven days prior to survey. In the six months before the survey, 37 percent of children age 6-59 months were given vitamin A supplements and 30 percent were given deworming medication. Ninety-four percent of children age 6-59 months are in households using iodized salt.

The percentage of children age 6-59 months given Vitamin A supplements in the last six months ranges from 20 percent in Lakshadweep and Manipur to 47 percent in Goa (**Table 10.18**).

## 10.6 NUTRITIONAL STATUS IN ADULTS

The 2019-21 NFHS collected anthropometric data on the height and weight of women age 15-49 and men age 15-54 years. These data were used to calculate several measures of nutritional status such as women's height and body mass index (BMI).

### Body mass index (BMI)

BMI is calculated by dividing weight in kilograms by height in metres squared (kg/m<sup>2</sup>).

| Status                    | BMI (kg/m <sup>2</sup> ) |
|---------------------------|--------------------------|
| Too thin for their height | <18.5                    |
| Normal                    | 18.5-24.9                |
| Overweight                | 25.0-29.9                |
| Obese                     | ≥30.0                    |

**Sample:** Women age 15-49 who are not pregnant and who have not had a birth in the two months before the survey and men age 15-49

Information on BMI of women is provided in **Table 10.19.1** and **Figure 10.6**. Nineteen percent of women age 15-49 are thin, 24 percent are overweight or obese, and 57 percent have a BMI in the normal range. Twelve percent of women age 15-49 years have a height below 145 cm.

**Trends:** The proportion of thin women age 15-49 declined from 23 percent in 2015-16 to 19 percent in 2019-21; at the same time, the proportion of overweight or obese women increased from 21 percent to 24 percent. Overall, there has been a slight increase in the mean BMI from 21.9 in 2015-16 to 22.4 in 2019-21. The proportion of women whose height was below 145 cm was the almost the same in 2015-16 (11.1) and 2019-21 (11.5) (**Figure 10.7**).

**Figure 10.6 Nutritional Status of Women and Men**

Percent distribution of women and men age 15-49

### Patterns by background characteristics

- The proportion of thin women decreases with age, from 40 percent for women age 15-19 to 9 percent for women age 40-49, whereas the proportion of overweight or obese women increases steadily, from 5 percent of women age 15-49 to 37 percent of women age 40-49.
- The proportion of thin women is higher in rural areas (21%) than in urban areas (13%) and the reverse is observed for the prevalence of overweight or obesity (33% in urban areas and 20% in rural areas).
- There is a steady decrease in the proportion of thin women as household wealth increases (from 28% in the lowest wealth quintile to 10% in the highest wealth quintile), which is accompanied by a steady increase in the proportion of overweight or obese women (from 10% in the lowest wealth quintile to 39% in the highest wealth quintile).
- The highest proportion of thin women is observed in Jharkhand and Bihar (26% each), followed by Gujarat and Dadra & Nagar Haveli and Daman & Diu (25% each). The highest proportion of overweight or obese women is found in Puducherry (46%), Chandigarh (44%), Delhi, Tamil Nadu, and Punjab (41% each), and Kerala and Andaman & Nicobar Islands (38% each) (**Table 10.20.1**).

## Figure 10.7 Trends in Nutritional Status

Percentage of women and men age 15-49

Sixteen percent of men age 15-49 are thin, 23 percent are overweight or obese, and 61 percent have a BMI in the normal range. The mean body mass index for men (22.4) is the same as that of women (22.4) (Table 10.19.2).

### Patterns by background characteristics

- The patterns of nutritional status by background characteristics among men are similar to those among women.
- The proportion of thin men decreases with age, from 41 percent of men age 15-19 to 8 percent of men age 40-49, whereas the proportion of overweight or obese men increases from 7 percent of men age 15-19 to 32 percent of men age 40-49.
- The proportion of thin men is higher in rural areas (18%) than in urban areas (13%), whereas 30 percent of men are overweight or obese in urban areas, compared with 19 percent in rural areas.
- There is steady decrease in the proportion of thin men with increasing household wealth (from 24% in the lowest wealth quintile to 9% in the highest wealth quintile), and a steady increase in the proportion of overweight or obese men (from 10% in the lowest wealth quintile to 37% in the highest wealth quintile).
- The proportion of thin men is highest in Bihar (22%), followed by Madhya Pradesh and Gujarat (21% each). The highest proportion of overweight or obese men is observed in Andaman & Nicobar Island (45%), followed by Puducherry (43%) and Lakshadweep (41%) (Table 10.20.2).

## 10.7 WAIST-TO-HIP RATIO IN ADULTS

- For the first time, the 2019-21 NFHS measured the waist circumference and hip circumference of women and men age 15-49 years.
- This information was used to calculate the waist-to-hip ratio (WHR). WHR helps to identify the distribution of body fat and predicts abdominal obesity. Abdominal obesity is associated with an increased risk of type 2 diabetes mellitus, myocardial infarction, stroke, and premature death.

### Waist-to-hip ratio (WHR)

WHR is calculated by dividing the waist measurement by the hip measurement. The formula is  $WHR = \text{waist circumference} / \text{hip circumference}$ . According to WHO, a healthy WHR is:

- 0.90 or less in men
- 0.85 or less in women

**Sample:** Women age 15-49 who are not pregnant and who have not had a birth in the two months before the survey and men age 15-49

- More than half (57%) of women and 48 percent of men have a waist-to-hip ratio (WHR) that puts them at a substantially increased risk of metabolic complications.

- The proportion of adults with an increased risk WHR increases with age, from 46 percent for women age 15-19 to 65 percent for women age 40-49, and from 28 percent for men age 15-19 to 60 percent for men age 40-49.
- The proportion of women having a substantially increased risk WHR is higher in urban areas than rural areas for both women (60% in urban area than 55% in rural area) and men (50% in urban area than 46% in rural area).
- The proportion of women having a substantially increased risk WHR is highest in Jammu & Kashmir (88%) and lowest in Madhya Pradesh (40%). For men it is highest in Chandigarh (67%) and lowest in Meghalaya (25%).

## 10.8 ANAEMIA PREVALENCE IN ADULTS

### Haemoglobin levels below which women and men are considered anaemic

| Respondents                                                                                                     | Haemoglobin level in grams/decilitre* |
|-----------------------------------------------------------------------------------------------------------------|---------------------------------------|
| Non-pregnant women age 15-49                                                                                    | <11.0                                 |
| Pregnant women age 15-49                                                                                        | <12.0                                 |
| Men age 15-49                                                                                                   | <13.0                                 |
| *Haemoglobin levels are adjusted for smoking, and for altitude in enumeration areas that are above 1,000 metres |                                       |

The same equipment and procedures used to measure anaemia in children were used to measure anaemia in women and men, except that capillary blood was collected exclusively from a finger prick.

Fifty-seven percent of women and 25 percent of men age 15-49 in India are anaemic (**Table 10.23.1** and **Table 10.23.2**). Twenty-six percent of women are mildly anaemic, 29 percent are moderately anaemic, and 3 percent are severely anaemic. Twenty percent of men are classified as mildly anaemic, 5 percent as moderately anaemic, and 0.4 percent as severely anaemic.

**Trends:** Anaemia prevalence has increased between NFHS-4 and NFHS-5, from 53 percent in 2015-16 to 57 percent in 2019-21 among women and from 23 percent in 2015-16 to 25 percent in 2019-21 among men (**Figure 10.8**).

### Patterns by background characteristics

- The overall prevalence of anaemia is consistently high, at more than 50 percent, in almost all of the subgroups of women. For men, the prevalence is above 20 percent in almost all of the subgroups.
- Anaemia varies by maternity status—61 percent of women who are breastfeeding are anaemic, compared with 52 percent of women who are pregnant and 57 percent of women who are neither pregnant nor breastfeeding.

### Figure 10.8 Trends in Anaemia Status

Percentage of women and men age 15-49

- The prevalence of anaemia generally decreases with schooling, from 59 percent among women with no schooling to 52 percent among women with 12 or more years of schooling. Across the same schooling groups, the prevalence of anaemia among men decreases from 32 percent to 19 percent.
- The proportion of anaemic women and men declines steadily as the wealth of the household increases (from 64% in the lowest wealth quintile to 51% in the highest wealth quintile among women and from 36% in the lowest wealth quintile to 18% in the highest wealth quintile among men).
- Women in urban areas are slightly less likely to be anaemic (54%) than those in rural areas (59%). The difference is larger for the prevalence of anaemia in men (27% in rural areas versus 20% in urban areas).

The prevalence of anaemia among women is 60 percent or more in Chhattisgarh, Bihar, Odisha, Gujarat, Jharkhand, Assam, Tripura, West Bengal, and the prevalence is less than one-third in Lakshadweep (26%), and Nagaland and Manipur (29% each). The prevalence of anaemia is also very high in the union territories of Ladakh (93%), Jammu & Kashmir (66%), Dadra & Nagar Haveli and Daman & Diu (63%), and Chandigarh (60%).

Anaemia prevalence in men is highest in Ladakh (76%), West Bengal (39%), Jammu & Kashmir (27%), and Assam (36%), and it is lowest in Lakshadweep and Manipur (6% each) and Chandigarh (9%).

## 10.8 FOOD CONSUMPTION OF WOMEN AND MEN

The consumption of a wide variety of nutritious foods is important for women's and men's health. A well-balanced diet is required for adequate amounts of protein, fat, carbohydrates, vitamins, and minerals. The 2019-21 NFHS asked women and men how often they consume various types of food (daily, weekly, occasionally, or never).

Among these food groups, women consume pulses and beans and dark green, leafy vegetables most often (**Table 10.26.1**). More than half (52%) of women consume dark green, leafy vegetables daily and an additional 39 percent consume them weekly. Almost half (50%) of women consume pulses or beans daily and 43 percent of women consume them weekly. Milk or curd is consumed daily by 49 percent of women daily and weekly by 24 percent of women, but 6 percent never consume milk or curd and 22 percent consume milk or curd only occasionally. Consumption of fruits is less common. Forty-nine percent of women consume fruits occasionally. Very few women consume chicken, meat, fish, or eggs daily, although about one-third of women consume these types of food weekly. Seven percent of women consume fried foods daily and 36 percent weekly. Aerated drinks are consumed daily by 3 percent of women and weekly by 13 percent of women (**Table 10.25**).

Men are less likely than women to completely abstain from eating chicken, meat, and fish. Overall, 29 percent of women and 17 percent of men are vegetarians according to this measure.

**Trends:** The pattern of daily food consumption has remained more or less the same since 2019-21 except there has been a decrease in the daily consumption of fried food and aerated drinks among both women and men.

### Patterns by background characteristics

- Deficiencies in the diet of both women and men are observed among those with little or no schooling, those in rural areas, those in poorer households, and those belonging to scheduled tribes. The most prominent deficiency in their diet is in fruits and milk or curd (**Table 10.26.1** and **Table 10.26.2**).
- The regular consumption of pulses and beans, as well as dark green, leafy vegetables, is common in every state (**Table 10.27.1** and **Table 10.27.2**).
- At least four-fifths of women eat dark green, leafy vegetables at least once a week in every state except Kerala (62%). The consumption of dark green, leafy vegetables among women at least once a week is also relatively low in the union territories of Lakshadweep (45%).
- The consumption of other types of food at least once a week among women varies widely across the states, particularly milk or curd (from 30% in Odisha and 36% in Mizoram to 92% in Ladakh, and 94% in Karnataka) and the women's consumption of fruits at least once a week ranges from 25% in Odisha to 93% in Goa.

## LIST OF TABLES

Note: Table is based on children who stayed in the household the night before the interview. Each of the indices is expressed in standard deviation (SD) units from the median of the WHO Child Growth Standards. Table is based on children with valid dates of birth (month and year) and valid measurement of both height and weight.

BMI = Body mass index

<sup>1</sup> Recumbent length is measured for children under age 2; standing height is measured for all other children

<sup>2</sup> Includes children who are below -3 standard deviations (SD) from the WHO Child Growth Standards population median

<sup>3</sup> Excludes children whose mothers were not interviewed

<sup>4</sup> First-born twins (triplets, etc.) are counted as first births because they do not have a previous birth interval

<sup>5</sup> For women who are not interviewed, information is taken from the Household Questionnaire. Excludes children whose mothers are not listed in the household schedule.

<sup>6</sup> Excludes children whose mothers were not weighed and measured, children whose mothers were not interviewed, and children whose mothers are pregnant or gave birth within the preceding 2 months. Mother's nutritional status in terms of BMI (Body Mass Index) is presented in Table 10.19.1.

Table 10.2 Nutritional status of children by state/union territory

Percentage of children under age 5 years classified as malnourished according to three anthropometric indices of nutritional status: height-for-age, weight-for-height, and weight-for-age, according to state/union territory, India, 2019-21

| State/union territory | Height-for-age <sup>1</sup> |                                     |                   |                        | Weight-for-height                   |                        |                   |                        | Weight-for-age                      |                        |                   |  |

Table 10.2 Nutritional status of children by state/union territory—Continued

Percentage of children under age 5 years classified as malnourished according to three anthropometric indices of nutritional status: height-for-age, weight-for-height, and weight-for-age, according to state/union territory, India, 2019-21

| State/union territory     | Height-for-age <sup>1</sup> |                                     |                   |  | Weight-for-height      |                                     |                        |                   | Weight-for-age         |                                     |                        |                   |

Note: Table is based on children who stayed in the household the night before the interview. Each of the indices is expressed in standard deviation (SD) units from the median of the WHO Child Growth Standards. Table is based on children with valid dates of birth (month and year) and valid measurements of both height and weight.

<sup>1</sup> Recumbent length is measured for children under age 2; standing height is measured for all other children

<sup>2</sup> Includes children who are below -3 standard deviations (SD) from the International Reference Population median

**Table 10.3 Trends in nutritional status of children**

Percentage of children under age 5 years classified as malnourished according to three anthropometric indices of nutritional status: height-for-age, weight-for-height, and weight-for-age, by residence, India, NFHS-5 and NFHS-4

| Measure of nutrition                | NFHS-5 (2019-21) |         |         | NFHS-4 (2015-16) |         |         |
|-------------------------------------|------------------|---------|---------|------------------|---------|---------|
|                                     | Urban            | Rural   | Total   | Urban            | Rural   | Total   |

Note: Table is based on last-born children born in the 2 years preceding the survey regardless of whether the children are living or dead at the time of the interview.

TBA = Traditional birth attendant

<sup>1</sup> Includes children who started breastfeeding within 1 hour of birth

<sup>2</sup> Children given something other than breast milk during the first 3 days of life

<sup>3</sup> Doctor, nurse, midwife, auxiliary nurse midwife, lady health visitor, or other health personnel

Table 10.5 Initial breastfeeding by state/union territory

Among last-born children who were born in the 2 years preceding the survey, percentage who were ever breastfed and percentages who started breastfeeding within 1 hour and within 1 day of birth; and among last-born children born in the 2 years preceding the survey who were ever breastfed, percentage who received a prelacteal feed in the first 3 days after birth, according to state/union territory, India, 2019-21

Note: Breastfeeding status refers to a "24-hour" period (yesterday during the day or at night). Children who are classified as breastfeeding and consuming plain water only consumed no liquid or solid supplements. The categories of not breastfeeding, exclusively breastfed, breastfeeding and consuming plain water, non-milk liquids/juice, other milk, and complementary foods (solids and semi-solids) are hierarchical and mutually exclusive, and their percentages add to 100 percent. Children who receive breast milk and non-milk liquids and who do not receive other milk and who do not receive complementary foods are classified in the non-milk liquid category even though they may also get plain water.

<sup>1</sup> Non-milk liquids include juice, juice drinks, clear broth, or other liquids

Table 10.7 Median duration of breastfeeding

Median duration of any breastfeeding, exclusive breastfeeding, and predominant breastfeeding among last-born children born in the 3 years preceding the survey, by background characteristics, India, 2019-21

| Background characteristic | Median duration (months) of breastfeeding among last-born children born in the past 3 years <sup>1</sup> |                         |                                        | Number of children |

Note: Median and mean durations are based on breastfeeding status of the child at the time of the survey (current status). Includes living and deceased children.

na = Not applicable

<sup>1</sup> For last-born children under age 24 months who live with the mother and are breastfeeding, information to determine exclusive and predominant breastfeeding comes from a 24-hour dietary recall. Tabulations assume that last-born children age 24 months or older who live with the mother and are breastfeeding are neither exclusively nor predominantly breastfed. It is assumed that last-born children not currently living with the mother and all non-last-born children are not currently breastfeeding.

<sup>2</sup> Either exclusively breastfed or received breast milk and plain water, and/or non-milk liquids only

**Table 10.8 Median duration of breastfeeding by state/union territory**

Median duration of any breastfeeding, exclusive breastfeeding, and predominant breastfeeding among last-born children born in the 3 years preceding the survey, percentage of children under 3 years using a bottle with a nipple, according to state/union territory, India, 2019-21

| State/union territory                | Median duration (months) of breastfeeding among last-born children born in the past 3 years <sup>1</sup> |                         |                                        | Percentage using a bottle with a nipple |

<sup>1</sup> For last-born children under age 24 months who live with the mother and are breastfeeding, information to determine exclusive and predominant breastfeeding comes from a 24-hour dietary recall. Tabulations assume that last-born children age 24 months or older who live with the mother and are breastfeeding are neither exclusively nor predominantly breastfed. It is assumed that last-born children not currently living with the mother and all non-last-born children are not currently breastfeeding.

<sup>2</sup> Either exclusively breastfed or received breast milk and plain water, and/or non-milk liquids only

Table 10.9 Foods and liquids consumed by children in the day or night preceding the interview

Percentage of youngest children under age 2 years living with the mother who consumed specific types of liquids and foods in the day or night preceding the interview, by breastfeeding status and age, India, 2019-21

Note: Breastfeeding status and food consumed refer to a "24-hour" period (yesterday during the day or at night).

<sup>1</sup> Other milk includes tinned, powdered, and fresh animal milk

<sup>2</sup> Does not include plain water. Includes juice, juice drinks, clear broth, or other non-milk liquids.

<sup>3</sup> Includes fortified baby food

<sup>4</sup> Includes pumpkin, carrots, squash, sweet potatoes that are yellow or orange inside, dark green leafy vegetables, ripe mangoes, papayas, cantaloupe, and jackfruit

**Table 10.10 Minimum acceptable diet**

Percentage of youngest children age 6-23 months living with their mother who are fed a minimum acceptable diet based on breastfeeding status, number of food groups, and times they were fed during the day or night preceding the interview, according to background characteristics, India, 2019-21

| Background characteristic | Among breastfed children 6-23 months, percentage fed: |                                     |                                      |                              |                                             | Among non-breastfed children 6-23 months, percentage fed: |                                     |                                      |                                  |                                                  | Among all children 6-23 months, percentage fed: |                                     |                                      |        |  | Number of all children |

| Children receive foods from 5 or more of the following food groups: : a. infant formula, milk other than breast milk, cheese or yogurt or other milk products; b. foods made from grains or roots, including porridge or gruel, fortified baby food; c. vitamin A-rich fruits and vegetables; d. other fruits and vegetables; e. eggs; f. meat, poultry, fish, shellfish, or organ meats; g. beans, peas, lentils, or nuts |                                                       |                                     |                                      |                              |                                             |                                                           |                                     |                                      |                                  |                                                  |                                                 |                                     |                                      |                        |  |
| For breastfed children, minimum meal frequency is receiving solid or semi-solid food at least twice a day for infants 6-8 months and at least three times a day for children 9-23 months                                                                                                                                                                                                                                   |                                                       |                                     |                                      |                              |                                             |                                                           |                                     |                                      |                                  |                                                  |                                                 |                                     |                                      |                        |  |
| Breastfed children age 6-23 months are considered to be fed a minimum acceptable diet if they are fed the minimum dietary diversity as described in footnote 1 and the minimum meal frequency as defined in footnote 2                                                                                                                                                                                                     |                                                       |                                     |                                      |                              |                                             |                                                           |                                     |                                      |                                  |                                                  |                                                 |                                     |                                      |                        |  |
| Includes two or more feedings of commercial infant formula, fresh, tinned and powdered animal milk, and yogurt                                                                                                                                                                                                                                                                                                             |                                                       |                                     |                                      |                              |                                             |                                                           |                                     |                                      |                                  |                                                  |                                                 |                                     |                                      |                        |  |
| For non-breastfed children age 6-23 months, minimum meal frequency is receiving solid or semi-solid food or milk feeds at least four times a day. At least one of the feeds must be a solid or semi-solid food.                                                                                                                                                                                                            |                                                       |                                     |                                      |                              |                                             |                                                           |                                     |                                      |                                  |                                                  |                                                 |                                     |                                      |                        |  |
| Non-breastfed children age 6-23 months are considered to be fed a minimum acceptable diet if they receive other milk or milk products at least twice a day, receive the minimum meal frequency as described in footnote 5, and receive solid or semi-solid foods from at least four food groups not including the milk or milk products food group                                                                         |                                                       |                                     |                                      |                              |                                             |                                                           |                                     |                                      |                                  |                                                  |                                                 |                                     |                                      |                        |  |
| Breastfeeding, or not breastfeeding and receiving two or more feedings of commercial infant formula, fresh, tinned, and powdered animal milk, and yogurt                                                                                                                                                                                                                                                                   |                                                       |                                     |                                      |                              |                                             |                                                           |                                     |                                      |                                  |                                                  |                                                 |                                     |                                      |                        |  |
| Children are fed the minimum recommended number of times per day according to their age and breastfeeding status as described in footnotes 2 and 5                                                                                                                                                                                                                                                                         |                                                       |                                     |                                      |                              |                                             |                                                           |                                     |                                      |                                  |                                                  |                                                 |                                     |                                      |                        |  |
| Children age 6-23 months are considered to be fed a minimum acceptable diet if they receive breastmilk, other milk or milk products as described in footnote 7, are fed the minimum dietary diversity as described in footnote 1, and are fed the minimum meal frequency as described in footnotes 2 and 5                                                                                                                 |                                                       |                                     |                                      |                              |                                             |                                                           |                                     |                                      |                                  |                                                  |                                                 |                                     |                                      |                        |  |

<sup>1</sup> Children receive foods from 5 or more of the following food groups: a. infant formula, milk other than breast milk, cheese or yogurt or other milk products; b. foods made from grains or roots, including porridge or gruel, fortified baby food; c. vitamin A-rich fruits and vegetables; d. other fruits and vegetables; e. eggs; f. meat, poultry, fish, shellfish, or organ meats; g. beans, peas, lentils, or nuts

<sup>2</sup> For breastfed children, minimum meal frequency is receiving solid or semi-solid food at least twice a day for infants 6-8 months and at least three times a day for children 9-23 months

<sup>3</sup> Breastfed children age 6-23 months are considered to be fed a minimum acceptable diet if they are fed the minimum dietary diversity as described in footnote 1 and the minimum meal frequency as defined in footnote 2

<sup>4</sup> Includes two or more feedings of commercial infant formula, fresh, tinned and powdered animal milk, and yogurt

<sup>5</sup> For non-breastfed children age 6-23 months, minimum meal frequency is receiving solid or semi-solid food or milk feeds at least four times a day. At least one of the feeds must be a solid or semi-solid food.

<sup>6</sup> Non-breastfed children age 6-23 months are considered to be fed a minimum acceptable diet if they receive other milk or milk products at least twice a day, receive the minimum meal frequency as described in footnote 5, and receive solid or semi-solid foods from at least four food groups not including the milk or milk products food group

<sup>7</sup> Breastfeeding, or not breastfeeding and receiving two or more feedings of commercial infant formula, fresh, tinned, and powdered animal milk, and yogurt

<sup>8</sup> Children are fed the minimum recommended number of times per day according to their age and breastfeeding status as described in footnotes 2 and 5

<sup>9</sup> Children age 6-23 months are considered to be fed a minimum acceptable diet if they receive breastmilk, other milk or milk products as described in footnote 7, are fed the minimum dietary diversity as described in footnote 1, and are fed the minimum meal frequency as described in footnotes 2 and 5

Table 10.11 Minimum acceptable diet by state/union territory

Percentage of youngest children age 6-23 months living with their mother who are fed a minimum acceptable diet based on breastfeeding status, number of food groups, and times they are fed during the day or night preceding the interview, according to state/union territory, India, 2019-21

| State/union territory | Among breastfed children 6-23 months, percentage fed: |                                     |                                      |                                             | Among non-breastfed children 6-23 months, percentage fed: |                                     |                                             |                                                  | Among all children 6-23 months, percentage fed: |                                     |                                      |                                      |

<sup>1</sup> Children receive foods from 5 or more of the following food groups: a. breast milk b. infant formula, milk other than breast milk, cheese or yogurt or other milk products; c. foods made from grains or roots, including porridge or gruel, fortified baby food made from grains; d. vitamin A-rich fruits and vegetables; e. other fruits and vegetables; f. eggs; g. meat, poultry, fish, shellfish, or organ meats; h. beans, peas, lentils, or nuts

<sup>2</sup> For breastfed children, minimum meal frequency is receiving solid or semi-solid food at least twice a day for infants 6-8 months and at least three times a day for children 9-23 months

<sup>3</sup> Breastfed children age 6-23 months are considered to be fed a minimum acceptable diet if they are fed the minimum dietary diversity as described in footnote 1 and the minimum meal frequency as defined in footnote 2

<sup>4</sup> Includes two or more feedings of commercial infant formula, fresh, tinned and powdered animal milk, and yogurt

<sup>5</sup> For nonbreastfed children age 6-23 months, minimum meal frequency is receiving solid or semi-solid food or milk feeds at least four times a day. At least one of the feeds must be a solid or semi-solid food.

<sup>6</sup> Nonbreastfed children age 6-23 months are considered to be fed a minimum acceptable diet if they receive other milk or milk products at least twice a day, receive the minimum meal frequency as defined in footnote 5, and receive solid or semi-solid foods from at least four food groups not including the milk or milk products food group

<sup>7</sup> Breastfeeding, or not breastfeeding and receiving two or more feedings of commercial infant formula, fresh, tinned, and powdered animal milk, and yogurt

<sup>8</sup> Children are fed the minimum recommended number of times per day according to their age and breastfeeding status as described in footnotes 2 and 5

<sup>9</sup> Children age 6-23 months are considered to be fed a minimum acceptable diet if they receive breast milk, other milk or milk products as described in footnote 7, are fed the minimum dietary diversity as described in footnote 1, and are fed the minimum meal frequency as described in footnotes 2 and 5

**Table 10.12 Prevalence of anaemia in children**

Percentage of children age 6-59 months classified as having anaemia, by background characteristics, India, 2019-21

| Background characteristic             | Anaemia status by haemoglobin level |                         |                    | Any anaemia (<11.0 g/dl) | Number of children |
|---------------------------------------|-------------------------------------|-------------------------|--------------------|--------------------------|--------------------|
|                                       | Mild (10.0-10.9 g/dl)               | Moderate (7.0-9.9 g/dl) | Severe (<7.0 g/dl) |                          |                    |
| <b>Age in months</b>                  |                                     |                         |                    |                          |                    |

| Total                                      | 29.2                                | 35.8           | 2.1         | 67.1         | 152,752  |

Note: Table is based on children who stayed in the household the night before the interview and who were tested for anaemia. Prevalence of anaemia, based on haemoglobin levels, is adjusted for altitude using the CDC formulas (Centers for Disease Control (CDC). 1998. Recommendations to prevent and control iron deficiency in the United States. *Morbidity and Mortality Weekly Report* 47 (RR-3): 1-29). Haemoglobin levels are shown in grams per decilitre (g/dl). Total includes mother who don't know their year of schooling.

<sup>1</sup> Excludes children whose mothers were not interviewed

<sup>2</sup> For mothers who are not interviewed, information is taken from the Household Questionnaire. Excludes children whose mothers are not listed in the household schedule.

<sup>3</sup> Mildly anaemic is 11.0-11.9 g/dl for non-pregnant women and 10.0-10.9 g/dl for pregnant women. Moderately/severely anaemic is  $<11.0$  g/dl for non-pregnant women and  $<10.0$  g/dl for pregnant women. Adjusted for altitude and for smoking status. Excludes children whose mother's anaemia status is not known.

Table 10.13 Prevalence of anaemia in children by state/union territory

Percentage of children age 6-59 months classified as having anaemia, according to state/union territory, India, 2019-21

| State/union territory                | Anaemia status by haemoglobin level |                         |                    | Any anaemia (<11.0 g/dl) |

Note: Table is based on children who stayed in the household the night before the interview and who were tested for anaemia. Prevalence of anaemia, based on haemoglobin levels, is adjusted for altitude using the CDC formulas (Centers for Disease Control (CDC). 1998. Recommendations to prevent and control iron deficiency in the United States. *Morbidity and Mortality Weekly Report* 47 (RR-3): 1-29). Haemoglobin levels are shown in grams per decilitre (g/dl).

**Table 10.14 Trends in prevalence of anaemia in children**

Percentage of children age 6-59 months classified as having anaemia by residence, NFHS-5 and NFHS-4, India

| Anaemia status by haemoglobin level | NFHS-5 (2019-21) |         |         | NFHS-4 (2015-16) |         |         |
|-------------------------------------|------------------|---------|---------|------------------|---------|---------|
|                                     | Urban            | Rural   | Total   | Urban            | Rural   | Total   |
| Mild (10.0-10.9 g/dl)               | 29.0             | 29.3    | 29.2    | 26.8             | 28.2    | 27.8    |
| Moderate (7.0-9.9 g/dl)             | 33.1             | 36.9    | 35.8    | 27.5             | 29.7    | 29.1    |
| Severe (<7.0 g/dl)                  | 2.2              | 2.1     | 2.1     | 1.6              | 1.5     | 1.5     |
| Any anaemia (<11.0 g/dl)            | 64.2             | 68.3    | 67.1    | 55.9             | 59.4    | 58.4    |
| Number of children                  | 42,917           | 109,835 | 152,752 | 56,240           | 148,757 | 204,997 |

Note: Table is based on children who stayed in the household the night before the interview. Prevalence of anaemia, based on haemoglobin levels, is adjusted for altitude using formulae in CDC (1998). Haemoglobin in g/dl = grams per decilitre.

Table 10.15 Presence of iodized salt in household

Among all households, percentage with salt tested for iodine content, percentage with salt in the household but the salt was not tested, and percentage with no salt in the household; and among households with salt tested, percentage with iodized salt, according to background characteristics, India, 2019-21

| Background characteristic            | Among households, percentage: |                                             |                               | Number of households | Among households with tested salt: |                      |
|--------------------------------------|-------------------------------|---------------------------------------------|-------------------------------|----------------------|------------------------------------|----------------------|
|                                      | With salt tested              | With salt, but salt not tested <sup>1</sup> | With no salt in the household |                      | Percentage with iodized salt       | Number of households |
| <b>Residence</b>                     |                               |                                             |                               |                      |                                    |                      |

<sup>1</sup> Includes households in which salt could not be tested for technical or logistical reasons

Table 10.17 Micronutrient intake among children

Among youngest children age 6-23 months who are living with their mother, percentages who consumed vitamin A-rich and iron-rich foods in the 24 hours preceding the survey; among all children age 6-23 months, percentage given micronutrient powder in the 7 days preceding the survey; among all children age 6-59 months, percentages who were given vitamin A supplements in the 6 months preceding the survey, who were given iron supplements in the 7 days preceding the survey, and who were given deworming medication in the 6 months preceding the survey; and among children age 6-59 months who live in households in which salt was tested for iodine, percentage in households using iodized salt, according to background characteristics, India, 2019-21

| Background characteristic               | Among youngest children age 6-23 months living with the mother:               |                                                                          |                    |                                                                | Among all children age 6-23 months: |                                                                      |                                                               | Among all children age 6-59 months:                                   |                    |                                                                |                    | Among children age 6-59 months living in households tested for iodized salt: |              |

Table 10.17 Micronutrient intake among children—Continued

Among youngest children age 6-23 months who are living with their mother, percentages who consumed vitamin A-rich and iron-rich foods in the 24 hours preceding the survey; among all children age 6-23 months, percentage given micronutrient powder in the 7 days preceding the survey; among all children age 6-59 months, percentages who were given vitamin A supplements in the 6 months preceding the survey, who were given iron supplements in the 7 days preceding the survey, and who were given deworming medication in the 6 months preceding the survey; and among children age 6-59 months who live in households in which salt was tested for iodine, percentage in households using iodized salt, according to background characteristics, India, 2019-21

| Background characteristic | Among youngest children age 6-23 months living with the mother:               |                                                                          |                    | Among all children age 6-23 months:                            |                    |                                                                      | Among all children age 6-59 months:                           |                                                                       |                    |                                                                | Among children age 6-59 months living in households tested for iodized salt: |  |

Table 10.17 Micronutrient intake among children—Continued

Among youngest children age 6-23 months who are living with their mother, percentages who consumed vitamin A-rich and iron-rich foods in the 24 hours preceding the survey; among all children age 6-23 months, percentage given micronutrient powder in the 7 days preceding the survey; among all children age 6-59 months, percentages who were given vitamin A supplements in the 6 months preceding the survey, who were given iron supplements in the 7 days preceding the survey, and who were given deworming medication in the 6 months preceding the survey; and among children age 6-59 months who live in households in which salt was tested for iodine, percentage in households using iodized salt, according to background characteristics, India, 2019-21

| Background characteristic | Among youngest children age 6-23 months living with the mother:               |                                                                          |                    | Among all children age 6-23 months:                            |                    |                                                                      | Among all children age 6-59 months:                           |                                                                       |                    | Among children age 6-59 months living in households tested for iodized salt: |                    |

na = Not applicable

<sup>1</sup> Includes meat and organ meats, fish, poultry, eggs, pumpkin, carrots, squash, sweet potatoes that are yellow or orange inside, dark green leafy vegetables, ripe mango, papaya, cantaloupe, and jackfruit

<sup>2</sup> Includes meat and organ meats, fish, poultry, and eggs

<sup>3</sup> Based on mother's recall

<sup>4</sup> Based on mother's recall and the vaccination card (where available)

<sup>5</sup> Deworming for intestinal parasites is commonly done for helminths and schistosomiasis

<sup>6</sup> Excludes children in households in which salt was not tested

<sup>7</sup> Excludes children whose breastfeeding status is unknown

Table 10.18 Micronutrient intake among children by state/union territory

Among youngest children age 6-23 months who are living with their mother, percentages who consumed vitamin A-rich and iron-rich foods in the 24 hours preceding the survey; among all children age 6-23 months, percentage given micronutrient powder in the 7 days preceding the survey; among all children age 6-59 months, percentages who were given vitamin A supplements in the 6 months preceding the survey, who were given iron supplements in the 7 days preceding the survey, and who were given deworming medication in the 6 months preceding the survey; and among children age 6-59 months who live in households in which salt was tested for iodine, percentage who live in households using iodized salt, according to state/union territory, India, 2019-21

| State/union territory | Among youngest children age 6-23 months living with the mother:               |                                                                          | Among all children age 6-23 months:                            | Among all children age 6-59 months:                                  |                                                               |                                                                       | Among children age 6-59 months living in households tested for iodized salt |

Table 10.18 Micronutrient intake among children by state/union territory—Continued

Among youngest children age 6-23 months who are living with their mother, percentages who consumed vitamin A-rich and iron-rich foods in the 24 hours preceding the survey; among all children age 6-23 months, percentage given micronutrient powder in the 7 days preceding the survey; among all children age 6-59 months, percentages who were given vitamin A supplements in the 6 months preceding the survey, who were given iron supplements in the 7 days preceding the survey, and who were given deworming medication in the 6 months preceding the survey; and among children age 6-59 months who live in households in which salt was tested for iodine, percentage who live in households using iodized salt, according to state/union territory, India, 2019-21

Table 10.18 Micronutrient intake among children by state/union territory—Continued

Among youngest children age 6-23 months who are living with their mother, percentages who consumed vitamin A-rich and iron-rich foods in the 24 hours preceding the survey; among all children age 6-23 months, percentage given micronutrient powder in the 7 days preceding the survey; among all children age 6-59 months, percentages who were given vitamin A supplements in the 6 months preceding the survey, who were given iron supplements in the 7 days preceding the survey, and who were given deworming medication in the 6 months preceding the survey; and among children age 6-59 months who live in households in which salt was tested for iodine, percentage who live in households using iodized salt, according to state/union territory, India, 2019-21

| State/union territory     | Among youngest children age 6-23 months living with the mother:               |                                                                          | Among all children age 6-23 months:                            |                                                                      | Among all children age 6-59 months:                           |                                                                 |                                                                |  | Among children age 6-59 months living in households tested for iodized salt |

| Smokes cigarettes/tobacco | 24.8                                  | 34.2                                     | 4.5                                | 63.5                                     | 27,983          |
| Does not smoke            | 25.7                                  | 28.5                                     | 2.6                                | 56.8                                     | 654,052         |
| Total                     | 25.6                                  | 28.7                                     | 2.7                                | 57.0                                     | 682,035         |
| NFHS-4 (2015-16)          | 24.7                                  | 26.0                                     | 2.4                                | 53.1                                     | 679,445         |

Note: Table is based on women who stayed in the household the night before the interview. Prevalence is adjusted for altitude and for smoking status, if known, using the CDC formulas (Centers for Disease Control (CDC). 1998. Recommendations to prevent and control iron deficiency in the United States. Morbidity and Mortality Weekly Report 47 (RR-3): 1-29). Haemoglobin levels are shown in grams per decilitre (g/dl).

<sup>1</sup> For pregnant women, the value is 10.0-10.9 g/dl

<sup>2</sup> For pregnant women, the value is 7.0-9.9 g/dl

<sup>3</sup> For pregnant women, the value is <7.0 g/dl

<sup>4</sup> For pregnant women, the value is <11.0 g/dl

Table 10.23.2 Prevalence of anaemia in men

Percentage of men age 15-49 with anaemia by background characteristics, India, 2019-21

| Background characteristic   | Men                      |                             |                       |                             | Number of men |
|-----------------------------|--------------------------|-----------------------------|-----------------------|-----------------------------|---------------|
|                             | Mild<br>(12.0-12.9 g/dl) | Moderate<br>(9.0-11.9 g/dl) | Severe<br>(<9.0 g/dl) | Any anaemia<br>(<13.0 g/dl) |               |

| Total age 15-49           | 20.2                     | 4.5                         | 0.4                      | 25.1                           | 84,822        |
| Age 50-54                 | 24.0                     | 7.2                         | 0.9                      | 32.1                           | 7,998         |
| Total age 15-54           | 20.5                     | 4.7                         | 0.4                      | 25.7                           | 92,820        |

Note: Table is based on men who stayed in the household the night before the interview. Prevalence is adjusted for altitude and for smoking status, if known, using the CDC formulas (Centers for Disease Control (CDC). 1998. Recommendations to prevent and control iron deficiency in the United States. Morbidity and Mortality Weekly Report 47 (RR-3): 1-29). Haemoglobin levels are shown in grams per decilitre (g/dl).

**Table 10.24 Prevalence of anaemia in women and men by state/union territory**

Percentage of women and men age 15-49 with anaemia by state/union territory, India, 2019-21

Note: Table is based on women and men who stayed in the household the night before the interview. Prevalence is adjusted for altitude and for smoking status, if known, using the CDC formulas (Centers for Disease Control (CDC). 1998. Recommendations to prevent and control iron deficiency in the United States. Morbidity and Mortality Weekly Report 47 (RR-3): 1-29). Haemoglobin levels are shown in grams per decilitre (g/dl).

<sup>1</sup> For pregnant women, the value is 10.0-10.9 g/dl <sup>2</sup> For pregnant women, the value is 7.0-9.9 g/dl <sup>3</sup> For pregnant women, the value is <7.0 g/dl <sup>4</sup> For pregnant women, the value is <11.0 g/dl

**Table 10.25 Women's and men's food consumption**

Percent distribution of women and men age 15-49 by frequency of consumption of specific foods, India, 2019-21

| Type of food                 | Frequency of consumption |        |              |       | Total | Number  |
|------------------------------|--------------------------|--------|--------------|-------|-------|---------|
|                              | Daily                    | Weekly | Occasionally | Never |       |         |
| WOMEN                        |                          |        |              |       |       |         |

## Key Findings

- **Prevalence of tuberculosis:** Based on reports from household respondents, 222 persons per 100,000 have medically treated tuberculosis. The prevalence of tuberculosis is higher among men (283 per 100,000) than among women (162 per 100,000).
- **Prevalence of goitre or any other thyroid disorder:** Based on self-reports, 3 percent of women age 15-49 have goitre or any other thyroid disorder.
- **Use of tobacco:** Thirty-nine percent of men and 4 percent of women age 15-49 use any form of tobacco.
- **Use of alcohol:** Twenty-two percent of men and 1 percent of women age 15-49 drink alcohol.
- **Coverage of health insurance or financing scheme:** At least one usual household member is covered under any health insurance or financing scheme in over two-fifths (41%) of households.

The health status of a population is reflected in the levels of morbidity and treatment seeking behaviour of its members. With the ongoing demographic and epidemiological transition in India, non-communicable diseases are now taking more of a toll on the health of the Indian population, while the problem of endemic and re-emerging infectious diseases still persists. This chapter presents data on some common infectious and important non-communicable diseases and their risk factors, health treatment seeking behaviour, tobacco and alcohol use, and coverage of health insurance. Prevalence estimates for tuberculosis (TB), diabetes, asthma, goitre or any other thyroid disorder, heart disease, and cancer are also provided.

## 11.1 TUBERCULOSIS

Tuberculosis has re-emerged as a major public health problem in many parts of the world, often as a concomitant illness to HIV/AIDS. Tuberculosis, once known as the 'White Plague', is contagious and spreads through droplets that can travel through the air when a person with the infection coughs, talks, or sneezes. In most developing countries, TB will continue to be a serious health threat even in the absence of HIV/AIDS due to the public health challenges posed by poor sanitation, poverty, and high illiteracy.

### 11.1.1 Prevalence of Tuberculosis

Based on reports from household respondents, 222 persons per 100,000 are estimated to have medically treated tuberculosis. The prevalence of tuberculosis is higher among men (283 per 100,000) than among women (162 per 100,000). Ninety-seven percent of reported tuberculosis cases are medically treated (**Table 11.1**).

**Trends:** Between 2015-16 and 2019-21, the overall prevalence of medically treated tuberculosis decreased from 305 persons per 100,000 to 222 persons per 100,000, and the prevalence among men decreased from 389 persons per 100,000 to 283 persons per 100,000. The prevalence among women decreased from 220 persons per 100,000 to 162 persons per 100,000. The overall decrease in prevalence for men and women combined is evident in all age and residence groups.

## Patterns by background characteristics

- Medically treated TB prevalence increases substantially with increasing age. The prevalence is more than twice as high among persons age 60 and above (567 persons per 100,000) as among persons age 15-59 (237 persons per 100,000) and 17 times as high as among children below age 15 (33 persons per 100,000).
- Medically treated TB prevalence is somewhat higher in rural areas (242 persons per 100,000) than in urban areas (179 persons per 100,000). Both sex and age differentials are more pronounced in rural areas than they are in urban areas (**Table 11.1**).
- Medically treated TB prevalence increases with levels of crowding, from 220 persons per 100,000 in households with fewer than three persons sleeping per room to 258 persons per 100,000 in households with seven or more persons sleeping per room (**Table 11.2**).
- There is a great deal of variation in the prevalence of medically treated TB according to the type of cooking fuel the household uses, ranging from a low of 179 persons per 100,000 usual residents in households using electricity, liquid petroleum gas, natural gas, or biogas to a high of 490 persons per 100,000 in households using straw, shrubs, or grass for cooking. High TB prevalence is also seen among households using other fuels not specified in the table (316 persons per 100,000).
- Medically treated TB prevalence is higher in households cooking in the house without having a separate room for cooking (291 persons per 100,000) than in households that cook in a separate room of the house (178 persons per 100,000) or in a separate building (258 persons per 100,000), but it is highest of all in households cooking in other places not specified in the table (357 persons per 100,000).
- Among the states, the number of persons suffering from medically treated TB ranges from a low of 24 persons per 100,000 in Chandigarh to a high of 634 persons per 100,000 in Sikkim, 626 persons per 100,000 in Meghalaya, 624 persons per 100,000 in Mizoram, and 616 persons per 100,000 in Nagaland (**Table 11.3**). In addition to Chandigarh, two states have prevalence below 120 persons per 100,000: Haryana (105 persons per 100,000) and Chhattisgarh (112 persons per 100,000).

### 11.1.2 Knowledge and Attitudes toward Tuberculosis

Despite being a curable disease, TB can still be a stigmatizing illness, due mainly to people's ignorance of its etiology and transmission. Ninety-three percent of women age 15-49 and 91 percent of men age 15-49 have heard of TB (**Table 11.4.1** and **Table 11.4.2**). In India, 70 percent of both women and men who have heard of TB correctly mentioned coughing or sneezing as a mode of transmission for TB. However, more than three-fifths of the population that has heard of TB have some misconceptions regarding its transmission. One in every six (16%) women and more than one in every five (23%) men report they would want the TB positive status of a family member to remain a secret. Ninety percent of women and 92 percent of men who have heard of TB believe that it can be cured.

**Trends:** The proportion of women who have heard of TB has slightly increased from 87 percent in 2015-16 to 93 percent in 2019-21, while that in men has increased from 88 percent to 91 percent. The proportion of women who report that TB is spread through the air by coughing and sneezing has remained almost the same (from 69% in 2015-16 to 70% in 2019-21), whereas the proportion decreased slightly for men from 72% in 2015-16 to 70% in 2019-21). In the same period, the knowledge that TB can be cured increased slightly from 89 percent to 90 percent among women and from 91 percent to 92 percent among men.

## Patterns by background characteristics

- The proportion of women who have heard of TB generally increases steadily with increases in schooling and the wealth index, from about 9 in 10 women in the lowest schooling and wealth categories to 97 percent in the highest schooling and wealth categories. The same pattern by schooling and the wealth index exists for men (**Table 11.4.1** and **Table 11.4.2**).
- Knowledge of TB transmission and knowledge that TB can be cured increases among women and men with increases in schooling and the wealth index.

- The percentage with misconceptions about the transmission of TB ranges from 43-68 percent of women and 35-66 percent of men in all subgroups of background characteristics.

## 11.2 HEALTH PROBLEMS

All interviewed women and men were asked whether they have diabetes, asthma, goitre or any other thyroid disorder, any heart disease, or cancer. **Table 11.5.1** and **Table 11.5.2** show the number of women and men age 15-49 per 100,000 who have any of these diseases by background characteristics.

The prevalence of diabetes, as reported by respondents, is 2 percent among both men and women age 15-49 years. The prevalence of asthma is 2 percent among women and 1 percent among men age 15-49 years. Similarly, goitre or any other thyroid disorder is more prevalent among women (3%) than men (0.5%). One percent of both women and men age 15-49 have any heart disease and less than 1 percent have cancer.

**Trends:** The prevalence of diabetes has remained unchanged among both women and men since 2015-16 (2% in 2015-16 and 2019-21). The prevalence of goitre or any other thyroid disorder among women increased slightly from 2 percent in 2015-16 to 3 percent in 2019-21, whereas the prevalence of asthma among both sexes and goitre or any other thyroid disorder among men remained almost unchanged.

### Patterns by background characteristics

- Although the above-mentioned diseases affect all age groups and are present across all groups of background characteristics, their prevalence increases with age.
- The prevalence of diabetes among women and men in the highest wealth quintile (3%) is higher than the prevalence among women and men in the lowest wealth quintile (1%). The prevalence of diabetes is also higher in urban areas than rural areas.
- The prevalence of diabetes is highest in the southern states, whereas that of goitre or any other thyroid disorder among women is relatively high in most of the northern and southern states.

## 11.3 USE OF TOBACCO

Tobacco use is associated with a wide range of diseases, including several types of cancers and heart and lung diseases, diabetes, eye disease, and rheumatoid arthritis. Studies have shown that in addition to sharing the same health risks as men, women who use tobacco experience difficulty in becoming pregnant and are at an increased risk of infertility, pregnancy complications, premature births, low birth-weight infants, stillbirths, miscarriages, and infant deaths

### 11.3.1 Consumption of Tobacco

Thirty-nine percent of men and 4 percent of women age 15-49 use some form of tobacco. The most common form of tobacco consumption among men is chewing *paan masala* or *gutkha* (15%), followed closely by smoking cigarettes (13%), using *khaini* (12%), and smoking *bidis* (7%). Among men who smoke cigarettes or *bidis*, 46 percent smoke 5 or more cigarettes or *bidis* each day on average. Among women, the most common form of tobacco used is chewing *paan masala* or *gutkha*, chewing *paan* with tobacco, and using *khaini* (1%) (**Table 11.7**).

### Figure 11.1 Tobacco Use by Sex and Residence

Percentage of women and men age 15-49

**Trends:** Use of any kind of tobacco decreased from 45 percent and 7 percent among men and women in 2015-16 to 39 percent and 4 percent among men and women, respectively, in 2019-21.

#### Patterns by background characteristics

- Among men as well as women, the use of any form of tobacco is higher in rural areas than in urban areas (**Figure 11.1**). Among men, in urban areas cigarettes are more popular than any other form of tobacco (**Table 11.8**).
- More than six in 10 men and about one-tenth of women with no schooling or less than 5 years of schooling use some form of tobacco. Tobacco use shows a substantial decrease with increasing levels of education among both men and women. However, almost one-fourth (24%) of men with 12 or more years of schooling use tobacco.
- There is an equally clear and continual decrease in tobacco use with increasing wealth quintiles. More than two in 10 (22%) men in the highest wealth quintile use tobacco, in comparison with 59 percent of men in the lowest wealth quintile. Nine percent of women in the lowest wealth quintile use tobacco.
- Women (11%) and men (52%) from scheduled tribes are more likely to use tobacco than those from any other caste/tribe group.

#### 11.3.2 Quitting Tobacco

The 2019-21 NFHS collected data on attempts to quit smoking or stop tobacco use in the 12 months preceding the survey by women and men age 15-49 who were using any kind of tobacco. Tobacco users who visited a doctor or other health care provider in the past 12 months were also asked whether they had received any advice to quit smoking or using tobacco in any form during the visits. All women and men age 15-49 were asked whether they were present when someone smoked in their home or elsewhere in the 30 days preceding the survey.

About 3 in 10 men and women who are tobacco users said they tried to stop smoking or using tobacco in any form in the 12 months preceding the survey. More than two-fifths (61%) of female and more than half (54%) of male tobacco users who visited a doctor or other health care provider in the 12 months preceding the survey were advised to stop smoking or using tobacco in any form. Nearly half (48%) of women and more than three-fifths (62%) of men were present when someone other than the respondent was smoking in their home or elsewhere in the 30 days preceding the survey (**Table 11.9**).

## 11.4 ALCOHOL USE, HEALTH INSURANCE, AND SOURCES OF HEALTH CARE

Information on alcohol use, health insurance coverage, and sources of health care among women and men are presented in this section. The reasons for not utilizing a government health facility, recent contacts with health personnel, matters discussed during contacts with health personnel, and problems in accessing health care are also discussed.

### 11.4.1 Use of Alcohol

Only 1 percent of women drink alcohol, compared with 22 percent of men. Among women who drink alcohol, 17 percent drink alcohol almost every day and 37 percent drink alcohol about once a week (**Table 11.11.1**). Among men who drink alcohol, 15 percent drink alcohol almost every day, 43 percent drink alcohol about once a week, and 42 percent drink less than once a week (**Table 11.11.2**). The percentage of women age 15-49 who drink alcohol is by far the highest among women in Arunachal Pradesh (18%) and Sikkim (15%). Alcohol use among men is highest in Goa (59%), Arunachal Pradesh (57%), and Telangana (50%) and is the lowest in Lakshadweep (1%) (**Table 11.12**).

**Trends:** The proportion of men who drink alcohol decreased, from 29 percent to 22 percent, between NFHS-4 in 2015-16 and NFHS-5 in 2019-21. During that period, the proportion of women who drink remained unchanged.

#### Patterns by background characteristics

- Drinking alcohol is more common among women from scheduled tribes (4%) than from any other caste/tribe group. Drinking is most common among Christian men (36%) and men belonging to "other" religions (49%), men with less than 5 years of schooling (33%), men from scheduled tribes (34%), and men age 35-49 (30%).

## 11.5 HEALTH INSURANCE COVERAGE

Health insurance coverage in India is far from satisfactory. Over two-fifths (41%) of households have at least one usual member covered under health insurance or financing scheme (**Table 11.13**). Only 30 percent of women age 15-49 and 33 percent of men age 15-49 are covered by health insurance or financing scheme. Almost half (46%) of those with insurance are covered by a state health insurance scheme and about one-sixth (16%) are covered by *Rashtriya Swasthya Bima Yojana* (RSBY). Three to six percent of women and 4-7 percent of men are covered by the Employee State Insurance Scheme (ESIS) or the Central Government Health Scheme (CGHS). The highest proportion of households covered under health insurance or financing scheme is found in Rajasthan (88%) and Andhra Pradesh (80%), and the lowest coverage (less than 15%) is in the Andaman & Nicobar Islands and Jammu & Kashmir (**Figure 11.2**).

**Trends:** The percentage of households in which at least one usual member is covered by health insurance or financing scheme increased from 29 percent to 41 percent between NFHS-4 and NFHS-5.

#### Patterns by background characteristics

- The percentage of households in which at least one usual member is covered by health insurance or financing scheme is highest in households with a Christian head of household (55%). The insurance coverage is slightly higher in rural areas (42%) than in urban areas (38%). Coverage is low among households whose head is a Sikh and households in the lowest wealth quintile.

## Figure 11.2 Health Insurance Coverage of Households by State/UT

Percentage of households with at least one member covered by a health scheme or health insurance

## 11.6 SOURCES OF HEALTH CARE

When household members get sick, they are slightly more likely to seek care in the public sector (50%) than the private sector (48%). Government and municipal hospitals are the most important source of health care in the public sector, providing services to 20 percent of households when household members get sick. In the private sector, private doctors and clinics are most frequently visited.

**Trend:** The percentage of households that use the public sector for health care increased from 45 percent in 2015-16 to 50 percent in 2019-21.

### Patterns by background characteristics

- The public health sector is the primary source of health care in rural areas (52%) and urban areas (47%). The private health sector is the main source of health care for 52 percent of households in urban areas and 46 percent of households in rural areas (**Table 11.16**).

## 11.7 REASONS FOR NOT USING GOVERNMENT HEALTH CARE

Half (50%) of households in India do not generally seek health care from the public sector. The percentage of households that do not generally use government health facilities is highest in Bihar (80%) and Uttar Pradesh (75%), and lowest (less than 5%) in Ladakh, Lakshadweep, and the Andaman & Nicobar Islands (**Table 11.17**). The most commonly reported reason for not using government health facilities at the national level is the poor quality of care (reported by 48% of households that do not generally use government facilities). The second most commonly reported reason is that the long waiting time at government facilities (46%), followed by the fact that there is no government facility nearby (40% of households).

## 11.8 RECENT CONTACT WITH HEALTH WORKERS

**Table 11.18** shows the percentage of women who had contact with a health worker in the three months preceding the survey by type of health worker. Women are more likely to have contacts with an ASHA (23%), an auxiliary nurse midwife (ANM) or a lady health visitor (LHV) (19%), or an *anganwadi* worker (AWW) (15%) than any other type of health worker. Among women who met with a health worker in the past three months, 73 percent met with a health worker at home, 68 percent met with a health worker at an *anganwadi* centre, and 39 percent met with a health worker at a health facility or camp.

Among ever-married women who had at least one contact with a health worker in the past three months, the majority discussed immunizations. Other common topics were treatment for a sick child, medical treatment for themselves, supplementary food, family planning, antenatal care, delivery care, and growth monitoring of a child. Never married women mostly discussed medical treatment for themselves, treatment for another person, menstrual hygiene, nutrition and health education, and disease prevention.

**Trend:** The percentage of women who contacted an ASHA doubled from 11 percent to 23 percent, an ANM/LHV increased from 14 percent to 19 percent, and an *anganwadi* worker (AWW) increased slightly from 14 percent to 15 percent from NFHS-4 to NFHS-5. Thirty-two percent of women had contact with any health worker in NFHS-5, compared with only 24 percent in NFHS-4.

### Patterns by background characteristics

- Recent contact with any health worker is more common for rural women (35%) than urban women (26%). Contact with any health worker is more common for currently married women (37%) than women who are widowed, divorced, separated, or deserted (24%) and never married women (17%).

## 11.9 PROBLEMS IN ACCESSING HEALTH CARE

NFHS-5 asked women age 15-49 about potential problems in obtaining medical treatment for themselves when they are sick. Three-fifths of women report at least one problem for themselves in obtaining medical care (**Table 11.21**). Over one-fifth (21%) of women cite money as a problem. Twenty-three percent of women cite the distance to a health facility and 22 percent cite having to take transport as a problem. Thirty-one percent of women report concerns that no female health provider is available. Thirty-nine percent of women report a concern that no provider is available and 40 percent that no drugs are available.

## LIST OF TABLES

For more information on morbidity, use of tobacco and alcohol, and health care, see the following tables:

| Tables        |                                                                                               |
|---------------|-----------------------------------------------------------------------------------------------|

<sup>1</sup> Misconceptions about the transmission of TB include that it can be spread by sharing utensils, by touching a person with TB, through food, through sexual contact, through mosquito bites, or through any other means except through the air when coughing or sneezing

Table 11.4.2 Knowledge and attitude toward tuberculosis: Men

Percentage of men age 15-49 who have heard of tuberculosis (TB), and among men who have heard of TB, percentage with specific knowledge and beliefs, according to background characteristics, India, 2019-21

| Background characteristic | Percentage<br>who have<br>heard of TB | Number<br>of men | Among men who have heard of TB, percentage who:                                 |                                                                       |                                    |                                                                                | Number<br>of men<br>who have<br>heard of TB |

<sup>1</sup> Employment information asked of only a sub-sample of women respondents

## Key Findings

- **Prevalence of hypertension:** Twenty-one percent of women and 24 percent of men age 15 and over have hypertension. Thirty-nine percent of women and 49 percent of men age 15 and over are pre-hypertensive.
- **Blood glucose levels:** Twelve percent of women and 14 percent of men age 15 and over have random blood glucose levels greater than 140 mg/dl.
- **Screening tests for cancer:** Among women age 15-49, 0.6 percent have had a screening test for breast cancer, 1.2 percent have had a screening test for cervical cancer, and 0.7 percent have had an oral cavity screening test.
- **Crude death rate:** The crude death rate (CDR) for India is 9 deaths per 1,000 population per year (10 per 1,000 for men and 8 per 1,000 for women). CDRs do not vary much across states, but they are highest in Odisha, Tamil Nadu, and Puducherry.
- **Age-specific death rates:** Age-specific death rates decrease from 15 deaths per 1,000 population age 0-4 to less than 1 death per 1,000 population age 10-14 and increase thereafter to a high of 79 deaths per 1,000 population at age 70 and over.
- **Cause of death:** The proportion of deaths that are due to non-medical reasons (accidents, violence, poisoning, homicides, or suicides) is higher among men (11%) than women (6%). The proportion of deaths due to non-medical reasons peaks at ages 15-29 for both men and women, reaching a high (47%) of all deaths for men age 20-29.

**N**on-communicable diseases (NCDs) account for 65 percent of all deaths in India. The major metabolic risk factors for NCDs are obesity, raised blood pressure, raised blood glucose, and raised total cholesterol levels in the blood. Household surveys that have a strong biomarker component are very important sources of information on non-communicable diseases and the associated risk factors. In addition to the measurement of waist and hip circumferences, the 2019-21 NFHS expanded the age range for measurement of blood pressure and blood glucose. This chapter provides information on the levels of blood pressure and random blood glucose, as well as health examinations for women and adult mortality.

## 12.1 COVERAGE OF TESTING FOR BLOOD PRESSURE AND RANDOM BLOOD GLUCOSE MEASUREMENTS

**Table 12.1** shows the coverage rates for measuring blood pressure and random blood glucose among eligible women and men by age group, residence, schooling, religion, caste/tribe, and household wealth. More than 89 percent of eligible women and 82 percent or more of eligible men age 15 and over had their blood pressure and random blood glucose measured.

Coverage of testing for blood pressure and random blood glucose is uniformly high in all groups, but coverage is slightly lower in urban areas than in rural areas for both women and men.

## 12.2 Blood Pressure

In the 2019-21 NFHS, for the first time the age range for measurement of blood pressure was expanded. The details of the measurement procedure have already been described in Chapter 1.

**Definition:** An individual is classified as having hypertension if he/she has a systolic blood pressure level greater than or equal to 140 mmHg, or a diastolic blood pressure greater than or equal to 90 mmHg, or he/she is currently taking antihypertensive medication to lower his/her blood pressure.

**Sample:** Women and men age 15 and over.

### 12.2.1 Self-Reports of Blood Pressure Measurement and Medication

**Table 12.2** shows data on self-reports of blood pressure measurement and medication among eligible women and men age 15 and over whose blood pressure was measured in NFHS-5. Sixty-seven percent of women and 54 percent of men say that their blood pressure was ever measured prior to the survey; 12 percent of women and 9 percent of men say that on two or more occasions they were told by a doctor or health professional that they have hypertension or high blood pressure. However, among diagnosed hypertensives only 7% of women and 6% of men are currently taking medicine to lower their blood pressure.

### 12.2.2 Blood Pressure Levels and Treatment Status

An individual is classified as having hypertension if that individual has a systolic blood pressure level greater than or equal to 140 mmHg or a diastolic blood pressure level greater than or equal to 90 mmHg or that individual is currently taking antihypertensive medication to lower his/her blood pressure.

Based on blood pressure measurement during the survey, 21 percent of women age 15 and over have hypertension, including 12 percent with mildly elevated blood pressure, 4 percent with moderately elevated blood pressure, and 2 percent with severely elevated blood pressure. Forty-four percent of women have blood pressure within the normal range. Almost two-fifths (39%) of women are pre-hypertensive. One percent of women are currently taking antihypertensive medicine and have their blood pressure in the normal range (**Table 12.3.1**).

The prevalence of hypertension is higher among men age 15 and over than among women age 15 and over. Twenty-four percent of men age 15 and over have hypertension, including 16 percent with mildly elevated blood pressure, 4 percent with moderately elevated blood pressure, and 2 percent with severely elevated blood pressure. Thirty percent of men have normal blood pressure and 49 percent are pre-hypertensive. About one percent of men are currently taking antihypertensive medicine and have their blood pressure in the normal range (**Table 12.3.2**).

## Patterns by background characteristics

- For both women and men, the prevalence of hypertension increases sharply with age. This increase is for all categories of hypertension, including pre-hypertension, for both women and men. About one-fourth of women and men age 40-49 have hypertension. Even at an earlier age, one in eight women and about one in five men age 30-39 have hypertension. (**Figure 12.1**).

**Figure 12.1 Prevalence of Hypertension by Age and Sex**

*Percentage of women and men age 15 and over*

- The prevalence of hypertension is higher among Sikhs (37% for men and 31% for women), Jains (30% for men and 25% for women), and Christians (29% for men and 26% for women) than the rest of the religions.
- There is a consistent and steep increase in the prevalence of hypertension with increases in the body mass index (BMI) for both women and men. Forty percent of obese men and 28 percent of obese women are hypertensive.
- The prevalence of hypertension among women is highest (35%) in Sikkim. The prevalence of hypertension among men age 15 and over ranges from 15 percent in Dadra & Nagar Haveli and Daman & Diu to 42 percent in Sikkim (**Table 12.4.1** and **Table 12.4.2**).
- For both women and men, the southern states have a higher prevalence of hypertension than the national average.

## 12.3 Random Blood Glucose

**Definition:** An individual is classified as having high blood glucose if he/she has a random blood glucose level of 141-160 mg/dl and very high blood glucose if he/she has a random blood glucose level of more than 160 mg/dl.

**Sample:** Women and men age 15 and over

The age range for measurement of random blood glucose was expanded to age 15 and above in 2019-21 NFHS. The details of the measurement procedure are discussed in Chapter 1. Random blood glucose is the measurement of blood glucose at any time without the necessity of fasting before the test.

Six percent of women age 15 and over have a high blood glucose level (141-160 mg/dl), and an additional 6 percent have a very high blood glucose level (more than 160 mg/dl), for a total of 12 percent of women whose blood glucose level exceeds 140 mg/dl. The prevalence of high blood glucose is slightly higher among men; 7 percent of men age 15 and over have a high blood glucose level, and an additional 7 percent have a very high blood glucose level, for a total of 14 percent. One percent of women, as well as men, age 15 and above have a normal blood glucose level and are taking medicine to lower their blood glucose level (**Table 12.5.1** and **Table 12.5.2**).

### Patterns by background characteristics

- The patterns of high blood glucose by background characteristics are quite similar to those for hypertension. For both women and men, the prevalence of high and very high blood glucose increases sharply with age.
- The combined prevalence of high and very high blood glucose is particularly pronounced among Christian men (18%) and Christian women (17%).
- There is a slight increase in very high blood glucose prevalence with an increase in household wealth for both women and men.
- Among the states, the prevalence of high and very high blood glucose (combined) among women age 15 and over ranges from 6 percent in Ladakh to 21 percent in Kerala. For men, the prevalence ranges from 7 percent each in Ladakh and Jammu & Kashmir to 22 percent in Goa and 24 percent in Kerala.

## 12.4 HEALTH EXAMINATIONS FOR CANCER SCREENING

The percentage of women age 15-49 years who have ever undergone specific screening tests for cancer (cancer of the cervix, breast, and oral cavity) are presented in this section (**Table 12.7** and **Table 12.8**). Overall, only 1.2 percent of women have had a cervical examination, 0.6 percent have had a breast examination, and 0.7 percent have had an examination of the oral cavity (**Figure 12.2**).

**Figure 12.2 Cancer Screening for Women**  
Percentage of women age 15-49

### Patterns by background characteristics

- As age increases, the likelihood of undergoing cancer screening increases, particularly for cervical examinations. The proportion of women undergoing a screening test for cervical cancer increases from just 0.3 percent among women age 15-19 years to 2 percent among women age 35-49 years.
- The percentage of women with an examination for screening breast cancer increases from 0.1 percent among women age 15-19 to 0.9 percent among women age 35-49. Older women are slightly more likely to have undergone an examination of the oral cavity for cancer screening (0.9%) than younger women (0.3%).
- All three types of health examinations are slightly more common in urban areas than in rural areas.
- The level of schooling among women does not make much of a difference for cervix, breast, and oral cavity examinations for cancer screening.
- Muslim women are slightly less likely than other women to undergo an examination of the cervix (0.8%), and Muslim and Sikh women are slightly less likely than other women to undergo a breast examination (0.4% each). Jain women are particularly likely to have undergone screening of the cervix (2.9%) and the oral cavity (3.4%) for cancer.
- The proportion of women receiving all three types of cancer screening increases steadily with the wealth quintile of the household, but the prevalence remains low in all wealth quintiles.
- Cervical examinations are particularly common in Tamil Nadu (7%), Puducherry (5%), and Mizoram (4%). The percentage of oral cavity examinations for cancer screening is highest in Andaman & Nicobar Islands (10%), followed by Andhra Pradesh (5%) and Telangana (2%) (**Table 12.8**).

## 12.5 AGE-SPECIFIC DEATH RATES AND CRUDE DEATH RATES

**Definition:** The crude death rate is the number of persons who were usual household members who died each year during the two years preceding the survey per 1,000 usual household members.

**Sample:** Women and men of all ages

### Patterns by background characteristics

- Age-specific death rates and crude death rates (CDRs) are based on the annual number of deaths reported for the *de jure* population during the two years preceding the survey. Rates are specified on a per thousand basis.
- The CDR for India is 9 deaths per 1,000 population (10 per 1,000 for men and 8 per 1,000 for women). The CDR is higher in rural areas than in urban areas (**Table 12.9**).
- The age-specific death rate (ASDR) is higher in the 0-4 age group (15 deaths per 1,000 population) than at age 5-9 (5 deaths per 1,000 population). The ASDR is lowest at age 10-14 (0.6 deaths per 1,000 population) and it remains low through age 40-44. Thereafter, the ASDR increases steadily to a high of 79 deaths per 1,000 population at age 70 or more. The pattern is similar for women and men in both urban and rural areas.
- The crude death rates (CDR) range from 5 deaths per 1,000 to 11 deaths per 1,000 across states/UTs in India. The CDR is less than the national average in northeastern, western, and northern states. The CDR in Meghalaya, Jammu & Kashmir, Dadra & Nagar Haveli and Daman & Diu, Lakshadweep and Nagaland is 5 per 1,000, whereas in Odisha, Puducherry and Tamil Nadu, the CDR is 11 per 1,000 (Table 12.10).

## 12.6 ADULT MORTALITY

The percentage of women and men who were usual residents of the household and who died in the two years preceding the survey by cause of death is presented in Table 12.11. The proportion of deaths due to non-medical reasons (i.e., deaths due to accidents, violence, poisoning, homicides, or suicides) is higher among men (11%) than women (6%). The proportion of deaths due to non-medical reasons is particularly high for men age 15-19 and 20-29 (42% and 47%, respectively) and women age 15-19 and 20-29 (31% and 21%, respectively).

## LIST OF TABLES

For more information on other adult health issues, see the following tables:

**Table 12.2 Self-reports of blood pressure measurement and medication**

Among eligible women and men age 15 and over whose blood pressure was measured in NFHS-5, percentage who say that their blood pressure was ever measured prior to the survey, percentage who say that on two or more occasions they were told by a doctor or health professional that they have hypertension or high blood pressure, and percentage who are currently taking medicine to lower their blood pressure, India, 2019-21

| Prior blood pressure measurement and blood pressure medication consumption                                                    | Women<br>Percentage | Number of<br>women | Men<br>Percentage | Number of<br>men | Total<br>Percentage | Number of<br>women and men |
|-------------------------------------------------------------------------------------------------------------------------------|---------------------|--------------------|-------------------|------------------|---------------------|----------------------------|
| Have ever had their blood pressure measured                                                                                   | 67.0                | 978,742            | 53.7              | 846,285          | 60.8                | 1,825,027                  |
| Have on two or more occasions been told by a doctor or health professional that they have hypertension or high blood pressure | 11.7                | 978,742            | 8.5               | 846,285          | 10.2                | 1,825,027                  |
| Are currently taking medicine to lower high blood pressure                                                                    | 7.4                 | 978,742            | 5.6               | 846,285          | 6.6                 | 1,825,027                  |

Table 12.3.1 Blood pressure levels and treatment status: Women

Among women age 15 and over, prevalence of hypertension, percent distribution of women by blood pressure levels, and percentage having normal blood pressure and taking medicine to lower their blood pressure, according to background characteristics, India, 2019-21

| Background characteristic | Prevalence of hypertension <sup>1</sup> | Normal                         |                                    | Pre-hypertensive                                    |                                                           | Hypertensive                                      |     |     | Percentage with normal blood pressure and taking medicine to lower their blood pressure | Number of women |

Table 12.3.1 Blood pressure levels and treatment status: Women—Continued

Among women age 15 and over, prevalence of hypertension, percent distribution of women by blood pressure levels, and percentage having normal blood pressure and taking medicine to lower their blood pressure, according to background characteristics, India, 2019-21

| Background characteristic     | Prevalence of hypertension <sup>1</sup> | Normal                         |                                    | Pre-hypertensive                                    |                                                           | Hypertensive                                      |     |  | Percentage with normal blood pressure and taking medicine to lower their blood pressure |  | Number of women |

SBP = Systolic blood pressure, the degree of force when the heart is pumping (contracting); DBP = Diastolic blood pressure, the degree of force when the heart is relaxed

BMI = Body mass index in kg/m<sup>2</sup>

<sup>1</sup> A woman is classified as having hypertension if she has SBP ≥140 mmHg or DBP ≥90 mmHg at the time of the survey, or she is currently taking medicine to lower her blood pressure.

<sup>2</sup> Told two or more times.

Table 12.3.2 Blood pressure levels and treatment status: Men

Among men age 15 and over, prevalence of hypertension, percent distribution of men by blood pressure levels, and percentage having normal blood pressure and taking medicine to lower their blood pressure, according to background characteristics, India, 2019-21

| Background characteristic | Prevalence of hypertension <sup>1</sup> | Normal                         |                                    | Pre-hypertensive                                    |                                                           | Hypertensive                                      |     | Percentage with normal blood pressure and taking medicine to lower their blood pressure |  | Number of men |

SBP = Systolic blood pressure, the degree of force when the heart is pumping (contracting); DBP = Diastolic blood pressure, the degree of force when the heart is relaxed

BMI = Body mass index in kg/m<sup>2</sup>

<sup>1</sup> A man is classified as having hypertension if he has SBP ≥140 mmHg or DBP ≥90 mmHg at time of survey, or he is currently taking medicine to lower his blood pressure.

Table 12.4.1 Blood pressure levels and treatment status by state/union territory: Women

Among women age 15 and over, prevalence of hypertension, percent distribution of women by blood pressure levels, and percentage having normal blood pressure and taking medicine to lower their blood pressure, according to state/union territory, India, 2019-21

| State/union territory | Normal                                  |                                |                                    | Pre-hypertensive                                    |                                                           |                                                   | Hypertensive |  |  | Percentage with normal blood pressure and taking medicine to lower their blood pressure |

SBP = Systolic blood pressure, the degree of force when the heart is pumping (contracting); DBP = Diastolic blood pressure, the degree of force when the heart is relaxed

<sup>1</sup> A woman is classified as having hypertension if she has SBP ≥140 mmHg or DBP ≥90 mmHg at the time of the survey, or she is currently taking medicine to lower her blood pressure.

**Table 12.4.2 Blood pressure levels and treatment status by state/union territory: Men**

Among men age 15 and over, prevalence of hypertension, percent distribution of men by blood pressure levels, and percentage having normal blood pressure and taking medicine to lower their blood pressure, according to state/union territory, India, 2019-21

| State/union territory | Prevalence of hypertension <sup>1</sup> | Normal                         |                                    | Pre-hypertensive                                    |                                                           | Hypertensive                                      |     |  | Percentage with normal blood pressure and taking medicine to lower their blood pressure |

SBP = Systolic blood pressure, the degree of force when the heart is pumping (contracting); DBP = Diastolic blood pressure, the degree of force when the heart is relaxed

<sup>1</sup> A man is classified as having hypertension if he has SBP ≥140 mmHg or DBP ≥90 mmHg at time of survey, or he is currently taking medicine to lower his blood pressure.

Table 12.5.1 Random blood glucose levels: Women

Among women age 15 and over, percent distribution of women by random blood glucose levels, percentage having normal blood glucose levels and taking medicine to lower their blood glucose level, and percentage having blood glucose levels  $\leq 140$  mg/dl and taking medicine to lower their blood glucose level, by background characteristics, India, 2019-21

| Background characteristic            | Random blood glucose values |                      |                        | Total | Percentage with normal blood glucose levels and taking medicine to lower their blood glucose level | Percentage with >140 mg/dl blood glucose levels or taking medicine to lower their blood glucose level | Number of women |

**Table 12.5.1 Random blood glucose levels: Women—Continued**

Among women age 15 and over, percent distribution of women by random blood glucose levels, percentage having normal blood glucose levels and taking medicine to lower their blood glucose level, and percentage having blood glucose levels  $\leq 140$  mg/dl and taking medicine to lower their blood glucose level, by background characteristics, India, 2019-21

| Background characteristic  | Random blood glucose values |                      |                        | Total | Percentage with normal blood glucose levels and taking medicine to lower their blood glucose level | Percentage with >140 mg/dl blood glucose levels or taking medicine to lower their blood glucose level | Number of women |
|----------------------------|-----------------------------|----------------------|------------------------|-------|----------------------------------------------------------------------------------------------------|-------------------------------------------------------------------------------------------------------|-----------------|
|                            | ≤140 mg/dl (normal)         | 141-160 mg/dl (high) | >160 mg/dl (very high) |       |                                                                                                    |                                                                                                       |                 |

Table 12.5.2 Random blood glucose levels: Men

Among men age 15 and over, percent distribution of men by random blood glucose levels and percentage having normal blood glucose levels and taking medicine to lower their blood glucose level, and percentage having blood glucose levels  $\leq 140$  mg/dl and taking medicine to lower their blood glucose level, by background characteristics, India, 2019-21

| Background characteristic            | Random blood glucose values |                      |                        | Total | Percentage with normal blood glucose levels and taking medicine to lower their blood glucose level | Percentage with >140 mg/dl blood glucose levels or taking medicine to lower their blood glucose level | Number of men |
|--------------------------------------|-----------------------------|----------------------|------------------------|-------|----------------------------------------------------------------------------------------------------|-------------------------------------------------------------------------------------------------------|---------------|
|                                      | ≤140 mg/dl (normal)         | 141-160 mg/dl (high) | >160 mg/dl (very high) |       |                                                                                                    |                                                                                                       |               |

Table 12.5.2 Random blood glucose levels: Men—*Continued*

Among men age 15 and over, percent distribution of men by random blood glucose levels and percentage having normal blood glucose levels and taking medicine to lower their blood glucose level, and percentage having blood glucose levels  $\leq 140$  mg/dl and taking medicine to lower their blood glucose level, by background characteristics, India, 2019-21

| Background characteristic  | Random blood glucose values |                      |                        | Total | Percentage with normal blood glucose levels and taking medicine to lower their blood glucose level | Percentage with >140 mg/dl blood glucose levels or taking medicine to lower their blood glucose level | Number of men |
|----------------------------|-----------------------------|----------------------|------------------------|-------|----------------------------------------------------------------------------------------------------|-------------------------------------------------------------------------------------------------------|---------------|
|                            | ≤140 mg/dl (normal)         | 141-160 mg/dl (high) | >160 mg/dl (very high) |       |                                                                                                    |                                                                                                       |               |

<sup>1</sup> Death due to accident, violence, poisoning, homicide or suicide

## Key Findings

- **Comprehensive knowledge of HIV/AIDS:** One-fifth (22%) of women and nearly one-third of men (31%) age 15-49 in India have comprehensive knowledge of HIV/AIDS.
- **Knowledge of mother-to-child transmission of HIV:** Seventy-three percent of women and 72 percent of men know that HIV can be transmitted during pregnancy; 70 percent of women and 68 percent of men know that HIV can be transmitted during delivery; and 69 percent of women and 62 percent of men know that HIV can be transmitted by breastfeeding.
- **Coverage of prior HIV testing:** Fifty-seven percent of women and 70 percent of men age 15-49 know where to obtain an HIV test. Twenty-one percent of women and 9 percent of men were tested for HIV prior to the survey.
- **Coverage of HIV testing during antenatal care (ANC) or labour:** Thirty-six percent of women who gave birth in the past 2 years had an HIV test during ANC or labour and received the test results.
- **Prevalence of sexually transmitted infections (STIs):** Twelve percent of women and 9 percent of men age 15-49 who have ever had sex reported having an STI and/or symptoms of an STI in the 12 months preceding the survey.
- **Comprehensive knowledge of HIV/AIDS among youth:** Twenty percent of young women and 29 percent of young men age 15-24 have a comprehensive knowledge of HIV.
- **Premarital sex among youth:** Two percent of never-married women and 7 percent of never-married men age 15-24 have ever had sexual intercourse in the last 12 months
- **Higher-risk sex among youth:** Thirty-nine percent of men age 15-24 who had sexual intercourse in the last 12 months had higher-risk intercourse (sex with a non-marital, non-cohabitating partner) in the 12 months preceding the survey, compared with 2 percent of women age 15-24.

**S**tarted in 1992, India's National AIDS Control Programme (NACP) has taken a comprehensive approach to the prevention and control of HIV/AIDS in India. Currently in its fourth round, key priorities of the programme now include the prevention of new infections; the provision of comprehensive care, support, and treatment for persons living with HIV; prevention of parent-to-child transmission; awareness-raising; reduction of stigma and discrimination; and demand generation for HIV services, particularly among women and youth.

This chapter presents findings from NFHS-5 on the current levels of HIV/AIDS knowledge and attitudes, prior HIV testing, and the prevalence of sexually transmitted infections (STIs), as well as sexual behaviour of the adult and youth population. Questions on HIV/AIDS were included only in the subsample of households selected for the state module.

## 13.1 HIV/AIDS KNOWLEDGE, TRANSMISSION, AND PREVENTION METHODS

In India, 87 percent of women and 94 percent of men have heard of HIV or AIDS (**Table 13.1**). Seventy-four percent of women and 88 percent of men in the lowest wealth quintile have heard of HIV or AIDS, compared with 96 percent of women and 98 percent of men in the highest wealth quintile (**Figure 13.1**). However, only 68 percent of women and 82 percent of men age 15-49 know that using condoms consistently can reduce the risk of getting HIV/AIDS. Seventy-one percent of women and 78 percent of men age 15-49 know that limiting sexual intercourse to one uninfected partner who has no other partners can reduce the risk of HIV/AIDS. Overall, 60 percent of women and 71 percent of men know that both consistent condom use and only having sex with one uninfected partner can prevent HIV/AIDS (**Table 13.2**).

**Figure 13.1 Knowledge of HIV or AIDS by Household Wealth**

*Percentage of women and men age 15-49*

Seventy-four percent of women and 78 percent of men say that people can get HIV/AIDS from blood products or blood transfusions. Seventy-four percent of women and 77 percent of men say that people can get HIV/AIDS by injecting drugs.

**Trends:** Since NFHS-4, knowledge of HIV/AIDS has increased more among women than men. For women, knowledge increased by 12 percentage points from 76 percent in NFHS-4, and for men, it increased by 5 percentage points from 89 percent in NFHS-4. Similarly, knowledge that condoms, if used consistently and limiting sexual intercourse to one uninfected partner who has no other partners can prevent HIV/AIDS has also increased, and the increase is greater for women (from 47% in NFHS-4 to 60%), than for men (from 69% in NFHS-4 to 71%).

### Patterns by background characteristics

- Knowledge of HIV or AIDS increases sharply with schooling for both women and men, from 76 percent among women and 86 percent among men with no schooling to 97-99 percent among women and men with 12 or more years of schooling. Similarly, knowledge that condoms if used consistently and limiting sexual intercourse to one uninfected partner who has no other partners can prevent HIV/AIDS increases from 47 percent among women and 56 percent among men with no schooling to 75 percent among women and 80 percent among men with 12 or more years of schooling (**Table 13.2**).
- Knowledge of HIV or AIDS, as well as ways of preventing HIV/AIDS, also increases with wealth. The percentage who have heard of HIV or AIDS increases from 76 percent for women and 86 percent for men who have no schooling to 97 percent women and 99 percent of men with 12 or more year of schooling complete. Forty-six percent of women and 60 percent of men in the lowest wealth quintile know the two methods of prevention, compared with 75 percent of women and 81 percent of men in the highest wealth quintile.

### Figure 13.2 Comprehensive Knowledge of HIV/AIDS by Schooling

Percentage of women and men age 15-49

- Knowledge of HIV or AIDS varies greatly by state. The percentage of women who know about HIV or AIDS ranges from only 74 percent of women in Dadra & Nagar Haveli and Daman & Diu to 99 percent in Manipur, Goa and Kerala. For men, knowledge ranges from 84 percent in Meghalaya to 100 percent in Goa and Manipur. Around half (54%) of women in Meghalaya and over three-fifths (63%) of men in Meghalaya and 65 percent of men in Andaman & Nicobar Islands know that HIV/AIDS can be prevented by using condoms (**Table 13.5**).

## 13.2 COMPREHENSIVE KNOWLEDGE

### Comprehensive knowledge of HIV/AIDS

Knowing that consistent use of condoms during sexual intercourse and having just one uninfected faithful partner can reduce the chances of getting HIV/AIDS, knowing that a healthy-looking person can have HIV/AIDS, and rejecting two common misconceptions about transmission or prevention of HIV/AIDS.

**Sample:** Women and men age 15-49

Fifty-four percent of women and 64 percent of men know that HIV/AIDS cannot be transmitted by mosquito bites; 45 percent of women and 59 percent of men know that HIV/AIDS cannot be spread by sharing food with a person who has AIDS; and two-thirds of women (67%) and 71 percent of men know that a healthy looking person can have HIV/AIDS.

About one-fifth of women (22%) and nearly one-third of men (31%) have comprehensive knowledge of HIV/AIDS (**Table 13.3.1** and **Table 13.3.2**).

**Trends:** Comprehensive knowledge of HIV/AIDS has been more or less stagnant for both women and men since NFHS-4.

### Patterns by background characteristics

- Comprehensive knowledge is higher in urban than in rural areas. Twenty-nine percent of women and 37 percent of men in urban areas have comprehensive knowledge about HIV/AIDS, compared with 18 percent of women and 27 percent of men in rural areas (**Table 13.3.1** and **Table 13.3.2**).
- Comprehensive knowledge about HIV/AIDS increases sharply with schooling (**Figure 13.2**) and wealth; however, there is no subgroup of women, except Jain women, in which more than 34 percent have comprehensive knowledge. Among Jain women, 47 percent have comprehensive knowledge. Among men, there is no subgroup in which more than 45 percent have comprehensive knowledge, with the exception of men belonging to other religions (57%) and Jains (64%).
- The percentage of women and men who have comprehensive knowledge of HIV/AIDS varies greatly by state. For women, comprehensive knowledge is highest in Mizoram (64%) and lowest in Bihar, Arunachal Pradesh and Uttar Pradesh (10-13%). For men, comprehensive knowledge is highest in Goa (67%) and lowest in West Bengal and Meghalaya (16% each) (**Table 13.5**).

- The percentage of women and men who know that HIV/AIDS can be prevented by using condoms varies greatly by state (**Figure 13.3.1** and **Figure 13.3.2**).

**Figure 13.3.1 Women's Knowledge of Condom Use for HIV/AIDS Prevention by State/UT**

Percentage of women age 15-49

**Figure 13.3.2 Men's Knowledge of Condom Use for HIV/AIDS Prevention by State/UT**

Percentage of men age 15-49

### 13.3 KNOWLEDGE ABOUT MOTHER-TO-CHILD TRANSMISSION

Increasing the level of general knowledge about transmission of HIV/AIDS from mother to child and reducing the risk of transmission using antiretroviral drugs are critical to reducing mother-to-child transmission (MTCT) of HIV/AIDS. To assess MTCT knowledge, respondents were asked whether HIV can be transmitted from a mother to her child during pregnancy, during delivery, and by breastfeeding. Women were also asked if a mother with HIV can reduce the risk of transmission to her baby by taking certain drugs during pregnancy.

Seventy-three percent of women know that HIV/AIDS can be transmitted during pregnancy, 70 percent know that it can be transmitted during delivery, and 69 percent know that it can be transmitted by breastfeeding (**Table 13.4**). Among men, 72 percent know that HIV/AIDS can be transmitted during pregnancy, 68 percent know that it can be transmitted during delivery, and 62 percent know that it can be transmitted by breastfeeding. Overall, 62 percent of women and 54 percent of men know all three modes of mother-to-child transmission of HIV/AIDS.

More than half of women (51%) and almost half of men (46%) know that HIV/AIDS can be transmitted from a mother to her baby and that the risk of transmission can be reduced by the mother taking special drugs.

#### Patterns by background characteristics

- Knowledge of the three modes of MTCT varies greatly by schooling, wealth, and religion. Across all women and men, knowledge is lowest for women belonging to the lowest wealth quintile (53%) and is lowest for men without schooling (47%), and is highest among women with 12 or more years of schooling (70%), women belonging to the Buddhist/Neo-Buddhist religion (70%) and Jain men (67%) (**Table 13.4**).
- Knowledge of MTCT varies across states. Women are least likely to know about the three modes of MTCT in Sikkim (42%), and Meghalaya and Dadra & Nagar Haveli and Daman & Diu (47% each), and most likely to know them in Karnataka (80%), and Goa (81%). Men are least likely to know about the three modes of MTCT in Andaman & Nicobar Islands (21%), Dadra & Nagar Haveli and Daman & Diu (34%) and Meghalaya (39%) and most likely to know them in Karnataka (70%) and Nagaland (74%) (**Table 13.5**).

## 13.4 ACCEPTING ATTITUDES TOWARD PEOPLE LIVING WITH HIV

### Accepting attitudes toward people living with HIV/AIDS

Respondents with accepting attitudes toward people living with HIV/AIDS are those who know about HIV/AIDS and agree with each of the seven following statements: a) they would care for a relative with HIV/AIDS in their own home; b) they would buy fresh vegetables from a shopkeeper or vendor who has HIV/AIDS; c) a female teacher who has HIV/AIDS but is not sick should be allowed to continue teaching in the school; d) they would not want to keep it secret that a family member got infected with HIV/AIDS; e) they would allow an HIV positive student to attend school with students who are HIV negative; f) they think that people living with HIV should be treated in the same public hospital with patients who are HIV negative; and g) they think that people living with HIV should be allowed to work in the same office with people who are HIV negative.

**Sample:** Women and men age 15-49 who know about HIV/AIDS

Widespread stigma and discrimination in a population can adversely affect both people's willingness to be tested and their adherence to antiretroviral therapy (ART) if needed. Thus, the reduction of stigma and discrimination in a population is an important indicator of the success of any programme targeting HIV/AIDS prevention and control.

A majority of both women and men agree with each of the different statements. Agreement varies for women from a low of 61 percent of women who agree that they would not want to keep secret that a family member was infected with HIV/AIDS to 71 percent each agreeing that a female teacher who has HIV/AIDS but is not sick should be allowed to continue teaching and they are willing to care for a relative with HIV/AIDS in their own home.

For men, agreement ranges from 59 percent who say that they would not want to keep secret that a family member got infected with HIV/AIDS to 76 percent who agree that a female teacher who has HIV/AIDS but is not sick should be allowed to continue teaching. Overall, however, only 23 percent of women and 24 percent of men express accepting attitudes toward people living with HIV/AIDS based on agreement with all seven specified statements (Table 13.6).

### Figure 13.4 Discriminatory Attitudes toward People Living with HIV/AIDS

Percentage of women and men age 15-49 who have heard of HIV or AIDS

About the same percentage of women (65-69%) and men (65-73%) agree that they would allow an HIV positive student to attend school with students who are HIV negative, that people living with HIV should be treated in the same public hospital with patients who are HIV negative, and that people living with HIV should be allowed to work in the same office with people who are HIV negative. However, 64 percent of women, compared with 69 percent of men, say that they would buy fresh vegetables from a shopkeeper or vendor who has HIV/AIDS (Figure 13.4).

### Patterns by background characteristics

- Accepting attitudes toward persons with HIV/AIDS based on agreement with each of the separate seven statements shows lower acceptance in rural than urban areas, except that a higher proportion of both women and men in rural areas than urban areas say that they would not want to keep secret that a family member was infected with

HIV/AIDS. Agreement with all seven statements, however, does not vary much by residence for women (22-25%) and men (23-26%) (**Table 13.6**).

- Accepting attitudes based on all seven statements vary greatly by state. For women, agreement with all seven statements varies from 7 percent in Meghalaya, 8 percent in Telangana, and 9 percent in Puducherry to 50 percent in Manipur (**Table 13.7.1**). For men, it ranges from 5 percent in Andhra Pradesh, 10 percent in Meghalaya, and 11 percent in Telangana to 60 percent in Manipur (**Table 13.7.2**).

### 13.5 ATTITUDES TOWARD NEGOTIATING SEX WITH HUSBAND

Being able to negotiate safe sex is critical to the prevention of HIV/AIDS and other sexually transmitted infections. In NFHS-5, women and men age 15-49 were asked if a wife is justified in refusing to have sexual intercourse with her husband if he has a sexually transmitted disease. Men were also asked if a wife is justified in asking her husband that they use a condom when they have sex if the husband has a sexually transmitted disease.

Eighty-seven percent of women and 83 percent of men age 15-49 agree that a wife is justified in refusing to have sex with her husband if he has a sexually transmitted disease. In addition, 87 percent of men agree that a wife is justified in asking her husband to use a condom if he has a sexually transmitted disease. Overall, 92 percent of men say that if a husband has a sexually transmitted disease, a wife can refuse to have sex with him or can request that they use a condom (**Table 13.8**).

#### Patterns by background characteristics

- There is very little variation by most background characteristics in women's and men's attitudes toward wives negotiating safer sex with their husbands (**Table 13.8**).
- Among women, agreement that a wife is justified in refusing to have sex with her husband if he has a sexually transmitted disease varies from a low of 70 percent in Arunachal Pradesh to a high of 96 percent in Delhi (**Table 13.9**).
- Sixty percent of men in Meghalaya, compared with 99 percent of men in Goa, agree that if a husband has a sexually transmitted disease, his wife is justified in asking that they use a condom.
- Men's agreement with either of the two statements varies similarly from a low of 63 percent in Meghalaya, 88 percent each in Telangana, and Kerala to a high of 100 percent in Goa.

### 13.6 MULTIPLE SEXUAL PARTNERS

#### Higher-risk sexual intercourse

Sexual intercourse with a partner who was neither a spouse nor who lived with the respondent.

**Sample:** Women and men age 15-49 who have had sexual intercourse in the 12 months preceding the survey

Having multiple sexual partners or having sex with a person who is neither a spouse nor a live-in partner can put women and men at higher risk of HIV/AIDS. In India, among those who had sexual intercourse in the 12 months preceding the survey, less than 1 percent (0.3%) of women and 1 percent of men reported having more than one sexual partner in the past 12 months, and less than 1 percent (0.5%) of women and 4 percent of men had intercourse in the past 12 months with a person who was neither their spouse or lived with them (**Table 13.10.1** and **Table 13.10.2**). Among women and men who had higher-risk sexual intercourse in the past 12 months, 57 percent of women and 60 percent of men reported use of a condom at last higher-risk sex. On average, women who have ever had sex have had 1.7 lifetime sexual partners and men who ever had sex have had 2.1 lifetime sexual partners.

#### Patterns by background characteristics

- Among women and men who had sex in the past 12 months, never married women and men are more likely than those who are currently married or formerly married to have intercourse in the past 12 months with a person who was neither their husband nor lived with them (**Table 13.10.1** and **Table 13.10.2**).

- Women and men who had sex in the past 12 months and were away from home for one month or more at a time in the past 12 months are more likely to have multiple partners than those who have not been away from home for one or more months (0.8% versus 0.3% for women; 2.6% versus 1% for men).
- Among women and men who had higher-risk sexual intercourse in the past 12 months, the use of a condom the last time they had higher-risk sex is much higher among those with 10 or more years of schooling than those with no schooling, as well as for men between those in the highest wealth quintile than those in the lowest wealth quintile.
- The percentage of men who had intercourse in the past 12 months with a person who was neither their wife nor lived with them among those who had sex in the past 12 months decreases with age from 6 percent among men age 15-24 to 1 percent among men age 40-49.
- Notably, 0.6 percent of men age 15-19 who had sex in the past 12 months had multiple sex partners and 4 percent had intercourse in the past 12 months with a person who was neither their wife nor lived with them. These proportions rises to 2 percent and 9 percent among men age 20-24.
- Two percent of men in Arunachal Pradesh, Himachal Pradesh, Punjab, Rajasthan, Jharkhand, Maharashtra, Telangana, Andhra Pradesh, Madhya Pradesh, Puducherry, Andaman & Nicobar Islands, and Delhi reported having more than one sexual partner in the past 12 months. The percentages were much lower in all other states (**Table 13.11**).

### 13.7 PAID SEX

Sexual intercourse undertaken for payment is most often at high risk of getting sexually transmitted diseases and limits the possibility for negotiating safe sex. Two percent of men age 15-49 in India say that they paid for sexual intercourse in the 12 months preceding the survey. About half (51%) of men who reported paying for sex in the past 12 months reported using a condom during their last paid sexual intercourse (**Table 13.12**).

#### Patterns by background characteristics

- Men who are divorced, separated, deserted, or widowed are more likely to have paid for sex (5%) in the 12 months preceding the survey than men who are never married (2%) or currently married (1%) (**Table 13.12**).
- Men who were away from home for one month or more at a time in the past 12 months are more likely than men staying at home to have paid for sex in the past 12 months (3% versus 1%).

### 13.8 COVERAGE OF HIV TESTING SERVICES

Knowledge of HIV status helps HIV negative individuals make decisions to reduce risk and increase safer sex practices in order to remain disease free. Among those who are living with HIV, knowledge of HIV status allows them to take action to protect their sexual partners, access care, and receive treatment.

#### 13.8.1 Awareness of HIV Testing Services and Experience with HIV Testing

Fifty-seven percent of women and 70 percent of men in India know where to obtain an HIV test. Women are about twice as likely as men to have ever been tested for HIV (21% versus 9%) and to have been tested in the 12 months before the survey and received the results of the last test (6% versus 3%) (**Table 13.13.1** and **Table 13.13.2**).

### Figure 13.5 Knowledge of Where to Get Tested for HIV by Schooling

Percentage of women and men age 15-49

**Trends:** There has been a substantial increase in HIV testing among women age 15-49 since NFHS-4. The proportion who had ever been tested for HIV prior to the survey increased from 16 percent in NFHS-4 to 21 percent in NFHS-5 among women and from 8 percent to 9 percent among men.

#### Patterns by background characteristics

- The proportion of women and men who know where to get an HIV test is lower in rural than urban areas and increases sharply with schooling and wealth (Table 13.13.1, Table 13.13.2, and Figure 13.5).
- Women are about twice as likely as men (19% versus 9%) to have ever been tested for HIV and received the results (Figure 13.6).
- The proportion of respondents who have ever been tested for HIV peaks at 33 percent among women age 25-29 and at 14 percent among men age 30-39.
- Urban women are more likely (29%) to have ever been tested for HIV than rural women (18%). Although urban men are also more likely than rural men to have ever been tested for HIV, the differential is smaller (12% versus 8%).
- Women's and men's likelihood of having ever been tested for HIV increases sharply with both schooling and wealth. For example, 12 percent of women and 4 percent of men with no schooling have ever been tested for HIV, compared with 30 percent of women and 14 percent of men with 12 or more years of schooling.
- HIV testing is more common among women and men who have been away from home for one month or more in the past 12 months (23% of women and 11% of men) than among those who have not been away (21% of women and 9% of men).
- The percentage of women and men who have ever been tested varies greatly by state. Among women, this percentage ranges from 7 percent in Uttar Pradesh and 8 percent each in Jharkhand and Bihar to 57 percent in Mizoram. Among men this percentage ranges from 1 percent in Lakshadweep and 2 percent in Assam to 36 percent in Mizoram (Table 13.14.1 and Table 13.14.2).
- The proportions of women and men who have been tested for HIV in the past 12 months and have received the results have the same pattern of variation by most background characteristics as do the proportions of women and men who have ever been tested for HIV.

### Figure 13.6 Prior HIV Testing

Percentage of women and men age 15-49

### 13.8.2 HIV Testing of Pregnant Women

**Table 13.15** presents information on self-reported HIV testing during pregnancy and labour among all women age 15-49 who gave birth in the two years before the survey. Twenty-two percent of women who received ANC for their last birth in the past two years received counselling on HIV and an HIV test during an antenatal care (ANC) visit and received the test results; 36 percent of women who had a birth in the past two years had an HIV test during ANC or labour and received the test results.

#### Patterns by background characteristics

- Women in urban areas are more likely than their rural counterparts to have an HIV test during ANC or labour and receive their test result (51% versus 31%) (**Table 13.15**).
- The percentage of women who had an HIV test during ANC or labour and who received their test results increases sharply with both schooling and wealth. For example, 16 percent of women in the lowest wealth quintile had an HIV test during ANC or labour and received the test results, compared with 56 percent of women in the highest wealth quintile (**Figure 13.7**).
- The percentage who had an HIV test during ANC or labour and who received their test results among women who had a birth in the two years preceding the survey and the percentage of women who received ANC for their last birth in the past two years who received counselling on HIV, an HIV test during ANC, and the test results vary greatly by state. For example, the proportion of women who received counselling on HIV, an HIV test during ANC, and their test results was the highest in Mizoram (66%), followed by Tamil Nadu (59%) and was the lowest in Jharkhand (5%) and Bihar (6%) (**Table 13.16**).

**Figure 13.7 HIV Testing during ANC or Labour  
Wealth by Household**

*Percentage of women who had a birth in the past two years who were tested for HIV during ANC or delivery for their most recent birth and received results*

## 13.9 SELF-REPORTING OF SEXUALLY TRANSMITTED INFECTIONS

### Sexually transmitted infections (STIs) and symptoms

Respondents who have ever had sex are asked whether they had an STI or symptoms of an STI (a bad-smelling, abnormal discharge from the vagina/penis, a genital sore, or a genital ulcer) in the 12 months before the survey.

**Sample:** Women and men age 15-49

Overall, 12 percent of women age 15-49 who have ever had sex and 9 percent of men age 15-49 who have ever had sex reported having an STI and/or symptoms of an STI in the past 12 months (**Table 13.17**).

#### Patterns by background characteristics

- Never married men are more likely than currently married or formerly married men to report having an STI and/or symptoms of an STI (**Table 13.17**).
- Self-reported STIs and/or symptoms of STIs do not vary greatly by residence or schooling for both women and men.
- Women and men who were away from home for one month or more at a time in the past 12 months are more likely to report an STI and/or symptoms of an STI in the past 12 months (18% of women and 14% of men) than women and men who were not away from home (12% of women and 9% of men).

- Self-reported STIs and/or symptoms of an STI in the past 12 months vary greatly across states, from a low among women of 4 percent in Odisha, 5 percent in Andhra Pradesh and 6 percent in Telangana to a high of 30 percent in Meghalaya. Among men range was from 1 percent in Mizoram, Goa, and Lakshadweep and 2 percent in Nagaland to a high of 23 percent in Ladakh, and 20 percent in West Bengal (**Table 13.18**).

## 13.10 HIV/AIDS-RELATED KNOWLEDGE AND BEHAVIOUR AMONG YOUNG PEOPLE

This section addresses HIV/AIDS-related knowledge among young people age 15-24 and also assesses the extent to which young people are engaged in behaviours that may place them at risk of contracting HIV.

### 13.10.1 Knowledge of HIV/AIDS

Knowledge of HIV transmission enables people to avoid HIV infection. This is especially true for young people, who are often at greater risk because they may have shorter relationships with more partners or engage in other high-risk behaviours.

In India, 20 percent of young women and 29 percent of young men age 15-24 have comprehensive knowledge of HIV, which includes knowing that consistent use of condoms during sexual intercourse and having just one uninfected faithful partner can reduce the chance of getting HIV, knowing that a healthy-looking person can have HIV, and rejecting two common misconceptions about HIV transmission (**Table 13.19**).

**Trends:** The percentage of young women with comprehensive knowledge about HIV has decreased only marginally from 22 percent in NFHS-4 to 20 percent in NFHS-5 and the proportion of young men with comprehensive knowledge has declined in the same period, from 32 percent to 29 percent (**Figure 13.8**).

**Figure 13.8 Trend in Comprehensive Knowledge among Youth**

Percentage of women and men age 15-24

### Patterns by background characteristics

- Comprehensive knowledge about HIV increases with age: only 17 percent of women and 24 percent of men age 15-17 have comprehensive knowledge, compared with 24 percent of women and 33 percent of men age 23-24 (**Table 13.19**).
- Young women and men in urban areas are more likely (26% of women and 34% of men) than their counterparts in rural areas (18% of women and 26% of men) to have comprehensive knowledge about HIV.
- Comprehensive knowledge among youth increases sharply with schooling and wealth. For example, 9 percent of women and 15 percent of men with no schooling have comprehensive knowledge, compared with 28 percent of women and 38 percent of men with 12 or more years of schooling.
- Comprehensive knowledge among youth varies greatly by state. Only 10 percent of women in Bihar and 12 percent in Uttar Pradesh and Tripura have comprehensive knowledge of HIV, compared with 69 percent in Mizoram. Similarly, only 14 percent of men in West Bengal and Meghalaya and 15 percent of men in Sikkim have comprehensive knowledge, compared with 73 percent in Goa and 60 percent in Mizoram (**Table 13.20**).

### 13.10.2 First Sex

**Table 13.21** provides information on the percentage of young women and men who have ever had sexual intercourse and who had sexual intercourse before the age of 15. Thirty-nine percent of women age 15-24 have ever had sex, compared with 21 percent of young men age 15-24. Two percent of young women and 0.5 percent of young men reported having sex before the age of 15.

**Trends:** Overall, the percentage of young people age 15-24 who have had sex before age 15 has decreased insignificantly between NFHS-4 and NFHS-5 for women (from 3% to 2%) and men (from 0.9% to 0.5%).

#### Patterns by background characteristics

- Among women age 15-24, the likelihood of ever having had sex and having had sex before age 15 declines sharply with schooling. Seventy-one percent of women with no schooling have ever had sex and 8 percent had sex before age 15, compared with 33 percent of women with 12 or more years of schooling having ever had sex and less than 1 percent having had sex before age 15 (**Table 13.21**).
- The likelihood of ever having had sex and having had sex before age 15 among women age 15-24 also varies greatly by wealth. The percentage who have ever had sex declines from 45 percent among women in the lowest wealth quintile to 28 percent among women in the highest wealth quintile, and the percentage who had sex before age 15 declines from 4 percent among women in the lowest wealth quintile to 0.4 percent among women in the highest wealth quintile.

#### 13.10.3 Premarital Sex

Ninety-seven percent of never married women and 89 percent of never married men age 15-24 have never had sexual intercourse (**Table 13.22**). Only 2 percent of never married women and 7 percent of never married men age 15-24 had sex in the past 12 months. Among never married women and men who had sex in the past 12 months, 63 percent of women and 62 percent of men reported the use of a condom at last sexual intercourse.

#### Patterns by background characteristics

- The percentage of never married women and men who have never had sexual intercourse decreases with age from 98 percent of women and 96 percent of men age 15-17 to 95 percent of women and 77 percent of men age 23-24 (**Table 13.22**).
- Never married men age 15-24, who were away from home for one month or more at a time in the past 12 months had more sexual intercourse in the past 12 months than men who were not away from home (11% versus 7%).

#### 13.10.4 Multiple Sexual Partners

Young men age 15-24 who had sexual intercourse in the past 12 months are much more likely than their female counterparts to have had higher-risk sexual intercourse in the 12 months preceding the survey (39% versus 2%). Among young women and men who had higher-risk sexual intercourse in the past 12 months, women were much more likely than men to have reported the use of a condom at last higher-risk intercourse (63% versus 58%) (**Table 13.23**).

#### Patterns by background characteristics

- Among young men who had sex in the past 12 months, the likelihood of having had higher-risk sex generally increases with schooling: 21-28 percent of men with no schooling or less than 5 years of schooling have had higher-risk sexual intercourse, compared with 57 percent of men with 12 or more years of schooling (**Tables 13.23**).
- Among women and men who had higher-risk sexual intercourse in the past 12 months, condom use at last sex with a non-marital, non-cohabitating partner is much higher in urban areas than in rural areas. Seventy-two percent of women and 64 percent of men in urban areas who had higher-risk sex in the past 12 months the use of a condom during their last sexual intercourse with their last non-marital, non-cohabitating partner, compared with 59 percent of women and 54 percent of men in rural areas.

#### 13.10.5 Coverage of HIV Testing Services

Seeking an HIV test may be more difficult for young people than older adults because many young people lack experience in accessing health services for themselves and because there are often barriers to young people in obtaining services. **Table 13.24** provides information on sexually active youth age 15-24 who have been tested for HIV and received the results of the last test.

Among young people age 15-24 who have had sexual intercourse in the past 12 months, the proportion who were tested for HIV and received their results was higher among women than among men; 13 percent of women were tested and received the results, compared with only 3 percent of men.

#### Patterns by background characteristics

- The proportion of young women tested for HIV and receiving the test results in the past 12 months among those who have had sexual intercourse in the past 12 months increases with age from 6 percent of women age 15-17 to 14 percent of women age 23-24 (**Table 13.24**).
- Young women age 15-24 in urban areas who had sex in the past 12 months are more likely to have been tested for HIV in the past 12 months and received the test results (15%) than their rural counterparts (12%). The percentage of young men who were tested for HIV in the past 12 months and received the test results was the same in urban and rural areas (3%).
- The percentage of young women and men who were tested for HIV in the past 12 months and who received their results tends to increase with both schooling and wealth.

## LIST OF TABLES

For more information on HIV/AIDS-related knowledge, attitudes, and behaviour, see the following tables:

| Tables        |                                                                                                                  |
|---------------|------------------------------------------------------------------------------------------------------------------|
| Table 13.1    | Knowledge of HIV or AIDS                                                                                         |
| Table 13.2    | Knowledge of HIV/AIDS prevention methods                                                                         |
| Table 13.3.1  | Comprehensive knowledge about HIV/AIDS: Women                                                                    |
| Table 13.3.2  | Comprehensive knowledge about HIV/AIDS: Men                                                                      |

<sup>1</sup> For women, visits to parental/in-laws' home excluded.

Table 13.2 Knowledge of HIV/AIDS prevention methods

Percentage of women and men age 15-49 who, in response to prompted questions, say that people can reduce the risk of getting HIV/AIDS by using condoms every time they have sexual intercourse and by having one uninfected sex partner who has no other sex partners, and percentage who say people can get HIV/AIDS from blood products or blood transfusions and by injecting drugs, by background characteristics, India, 2019-21

| Background characteristic                                                             | Percentage who say that people can reduce the risk of getting HIV/AIDS by: |                                                                        |                                                                                            |                                                                                     |                                                                    | Percentage who say that people can get HIV/AIDS from blood products or transfusions | Percentage who say that people can reduce the risk of getting HIV/AIDS by: |                            |                                                                        |                                                                                            |                                                                                     | Number of men |                                                                    |

<sup>1</sup> Respondents who know how to prevent HIV/AIDS say that the consistent use of a condom for every act of sexual intercourse and having just one uninfected faithful sex partner can reduce the chance of getting HIV/AIDS

<sup>2</sup> Respondents with a comprehensive knowledge say that consistent use of condoms every time they have sex and having just one uninfected faithful sex partner can reduce the chance of getting HIV/AIDS, say that a healthy-looking person can have HIV/AIDS, and reject two common misconceptions about transmission or prevention of HIV/AIDS.

<sup>1</sup> Respondents who know how to prevent HIV/AIDS say that the consistent use of a condom for every act of sexual intercourse and having just one uninfected faithful sex partner can reduce the chance of getting HIV/AIDS

<sup>2</sup> Respondents with a comprehensive knowledge say that consistent use of a condom every time they have sex and having just one uninfected faithful sex partner can reduce the chance of getting HIV/AIDS, say that a healthy-looking person can have HIV/AIDS, and reject two common misconceptions about transmission or prevention of HIV/AIDS

Table 13.4 Knowledge of prevention of HIV/AIDS transmission from a mother to her baby

Percentage of women and men who know that HIV/AIDS can be transmitted from a mother to her baby during pregnancy, during delivery, by breastfeeding and by all three means, and that the risk of HIV/AIDS transmission from a mother to her baby can be reduced by the mother taking special drugs, by background characteristics, India, 2019-21
